#### Abstract

Wave function is important for determining decay constants $f_{\mathrm{D}_{\mathrm{S}}}$ and $f_{\mathrm{D}^{-}}$．Using the 5 types of D meson wave functions in the heavy quark limit，we studied the uncertainties of radiative pure－leptonic decays of $\mathrm{D}_{\mathrm{S}}^{-}\left(\mathrm{D}^{-}\right)$mesons．The branching ratios are（1．025390－1．706812）$\times 10^{-5}$ and $(0.953498-1.576725) \times 10^{-6}$ for $\mathrm{D}_{\mathrm{S}}^{-}$and $\mathrm{D}^{-}$decays，respectively，which are sensitive to the type of wave function．

Key words：D decay，wave function，branching ratio

## 1 Introduction

The pure－leptonic decays of heavy meson are use－ ful to determine the meson decay constants，and they are also sensitive to new physics beyond the Standard Model（SM）［1－3］．Many decays of B meson have been researched not only in theory but also by exper－ iment，such as $\mathrm{B}^{0}\left(\mathrm{~B}_{\mathrm{S}}\right) \rightarrow \gamma \nu \bar{v}$ ，their branching ratios are about $0.7 \times 10^{-9}\left(2.4 \times 10^{-8}\right) ; \mathrm{B}^{0}\left(\mathrm{~B}_{\mathrm{S}}\right) \rightarrow \gamma \mu^{+} \mu^{-}$ are about $0.65 \times 10^{-10}\left(1.7 \times 10^{-9}\right) ; \mathrm{B}^{0}\left(\mathrm{~B}_{\mathrm{S}}\right) \rightarrow \gamma \mathrm{e}^{+} \mathrm{e}^{-}$ are about $0.83 \times 10^{-10}\left(1.9 \times 10^{-9}\right)[4,5]$ ．But there is less research on the pure－leptonic decays of $\mathrm{D}_{\mathrm{S}}^{-}\left(\mathrm{D}^{-}\right)$． As the heavy meson， D meson also plays an impor－ tant role in determining the meson decay constants and other parameters．The pure－leptonic decays of $D_{S}^{-}\left(\mathrm{D}^{-}\right)$may be sensitive to establishing new physics beyond the SM．But due to the small mass of lep－ tons，they are helically suppressed by $m_{1}^{2} / m_{\mathrm{D}_{\mathrm{S}}}^{2}$ ．For－ tunately，similar to the pure－leptonic decays of B mesons，it will be overcome by a photon radiated from the charged particles at the cost of the electromag－ netic suppression with coupling constant $\alpha[6-8]$ ．

A pilot study has been carried out in Refs．［7，9－ 11］．However，either they calculate only one dominant diagram，or their results are not consistent with each other．In Ref．［12］，we find that different diagrams in $\mathrm{B}^{-}$decay are $\Gamma_{\mathrm{a}}: \Gamma_{\mathrm{b}}: \Gamma_{\mathrm{c}}: \Gamma_{\mathrm{a}+\mathrm{b}+\mathrm{c}}=1.40: 0.0005: 0.04: 1$ ，
obviously $\Gamma_{\mathrm{a}}$ is the dominant diagram compared with the other ones．So，it is enough to calculate only one dominant diagram and to neglect the others in the case of $\mathrm{B}^{-}$decay．But in the $\mathrm{D}_{\mathrm{S}}$ decay，the ratio is $\Gamma_{\mathrm{a}}: \Gamma_{\mathrm{b}}: \Gamma_{\mathrm{c}}: \Gamma_{\mathrm{a}+\mathrm{b}+\mathrm{c}}=14.72: 3.47: 17.32: 1$ and the ratio of the $\mathrm{D}^{-}$decay is $\Gamma_{\mathrm{a}}: \Gamma_{\mathrm{b}}: \Gamma_{\mathrm{c}}: \Gamma_{\mathrm{a}+\mathrm{b}+\mathrm{c}}=7.30: 0.94: 6.03: 1$ ． So，the contribution of all three diagrams is large and cannot be neglected．Then，unlike the pure leptonic decays，which only depend on the meson decays con－ stant，the radiative leptonic decays of $\mathrm{D}_{\mathrm{S}}^{-}\left(\mathrm{D}^{-}\right)$de－ pend on the structure of the meson wave function heavily［4］．This makes the theoretical prediction on this type of decay more difficult with hadronic uncer－ tainty．However，it also provides useful information about meson wave functions，which are essential for non－leptonic D decays．

In 2003，LÜ Cai－Dian et al．calculated all dia－ grams that are about the decays of $\mathrm{D}_{\mathrm{S}}^{-}\left(\mathrm{D}^{-}\right) \rightarrow \gamma \mathrm{l} \bar{v}$ $(\mathrm{l}=\mathrm{e}, \mu)$ at the tree level，using the non－relativistic constituent quark model［12］．However，they did not research the uncertainties in these decays due to the parameters and wave functions．In this paper， we will study the uncertainties in radiative decays $\mathrm{D}_{\mathrm{S}}^{-}\left(\mathrm{D}^{-}\right) \rightarrow \gamma \mathrm{l} \bar{v}$ ，which are due to the D meson wave functions $\phi_{\mathrm{D}}^{\mathrm{i}}(i=\mathrm{GEN}, \mathrm{GN}, \mathrm{KKQT}, \mathrm{KLS}$ ，Huang）and the parameters in them．In the next section，we an－ alyze the decays of $D_{S}^{-}\left(D^{-}\right) \rightarrow \gamma \mathrm{l} \bar{v}(\mathrm{l}=\mathrm{e}, \mu)$ and use

[^0]the wave functions to calculate their decay width. In Section 3, we give the numerical results and a brief conclusion. Finally, we provide a summary.

## 2 Theory and calculation

The calculation of D meson decay requires the hadronization of $\bar{c} s$ into a $D$ meson, which is the $D$ meson light cone wave function. So, light-cone wave function of the meson is needed in the calculation. The $\mathrm{D}_{\mathrm{S}}^{-}$meson and $\mathrm{D}^{-}$meson have a similar structure of wave function, except for different values of parameters characterizing a small $S U(3)$ breaking effect. In general, the two-particle light-cone distribution amplitudes of D meson, up to twist- 3 accuracy, are defined by [13]

$$
\begin{align*}
\int \frac{\mathrm{d}^{4} \omega}{(2 \pi)^{4}} \mathrm{e}^{\mathrm{i} k \omega}\langle 0| \bar{c}(0) s(\omega)\left|\mathrm{D}_{\mathrm{S}}^{-}\right\rangle & \begin{array}{l}
\text { tude. As for the momentum distribution amplitude } \\
\phi_{\mathrm{D}}(x, b), \text { we collect it as below }[13,15,16]
\end{array} \\
\phi_{\mathrm{D}}^{\mathrm{GEN}}(x, b) & =\frac{1}{2 \sqrt{2 N_{\mathrm{C}}}} f_{\mathrm{D}} 6 x(1-x)\left[1+C_{\mathrm{D}}(1-2 x)\right]  \tag{4}\\
\phi_{\mathrm{D}}^{\mathrm{MGEN}}(x, b) & =\frac{1}{2 \sqrt{2 N_{\mathrm{C}}}} f_{\mathrm{D}} 6 x(1-x)\left[1+C_{\mathrm{D}}(1-2 x)\right] \exp \left(-\frac{\omega^{2} b^{2}}{2}\right)  \tag{5}\\
\phi_{\mathrm{D}}^{\mathrm{GN}}(x, b) & =\frac{1}{2 \sqrt{2 N_{\mathrm{C}}}} f_{\mathrm{D}} N_{\mathrm{D}} x \exp \left(-\frac{x M_{\mathrm{D}}}{\omega}\right) \frac{1}{1+b^{2} \omega^{2}},  \tag{6}\\
\phi_{\mathrm{D}}^{\mathrm{KKQT}}(x, b) & =\frac{1}{2 \sqrt{2 N_{\mathrm{C}}}} f_{\mathrm{D}} N_{\mathrm{D}}(1-x) \theta(1-x) \theta\left(\frac{2 \Lambda_{\mathrm{D}}}{M_{\mathrm{D}}}+x-1\right) J_{0}\left[b \sqrt{\left.(1-x) \frac{2 \Lambda_{\mathrm{D}}}{M_{\mathrm{D}}}+x-1\right]}\right]  \tag{7}\\
\phi_{\mathrm{D}}^{\mathrm{KLS}}(x, b) & =\frac{1}{2 \sqrt{2 N_{\mathrm{C}}}} f_{\mathrm{D}} N_{\mathrm{D}} \sqrt{x(x-1)} \exp \left[-\frac{1}{2}\left(\frac{x M_{\mathrm{D}}}{\omega}\right)^{2}-\frac{\omega^{2} b^{2}}{2}\right]  \tag{8}\\
\phi_{\mathrm{D}}^{\mathrm{Huang}}(x, b) & =\frac{1}{2 \sqrt{2 N_{\mathrm{C}}}} f_{\mathrm{D}} N_{\mathrm{D}} x(1-x) \exp \left(-\Lambda_{\mathrm{D}} \frac{(1-x) m_{\mathrm{d}}^{2}+m_{\mathrm{c}}^{2}}{x(1-x)}\right) \tag{9}
\end{align*}
$$

where $J_{0}$ is the Bessel function, $f_{\mathrm{D}}$ is the D meson decay constant and variable $x$ is the mentum fraction of the light quark in the D meson. The first model $\phi_{\mathrm{D}}^{\mathrm{GEN}}$ is the Gegenbauer polynomial-like form, and $C_{\mathrm{D}}=0.7$. That the second candidate model $\phi_{\mathrm{D}}^{\mathrm{MGEN}}$ has an additional exponential term is for keeping the $k_{\perp}$ dependent. The third one $\phi_{\mathrm{D}}^{\mathrm{GN}}$ is an exponential model, and the fourth model $\phi_{\mathrm{D}}^{\mathrm{KKQT}}$ is obtained by solving the equations of motion without three-parton contributions, which were first proposed for the B meson, with $\Lambda_{\mathrm{D}}=0.75$. Here we use the heavy quark symmetry and modify the parameters to make them D meson DAs. The fifth model $\phi_{\mathrm{D}}^{\mathrm{KLS}}$ is a Gaussian type model. The sixth DA (we find it in the paper written by Huang, so we call it $\phi_{\mathrm{D}}^{\text {Huang }}$ ) is derived from the BHL prescription, with $m_{\mathrm{d}}=0.37 \mathrm{GeV}$, $m_{\mathrm{c}}=1.5 \mathrm{GeV}$. In the above candidate DAs, only

$$
\begin{align*}
= & -\frac{\mathrm{i}}{\sqrt{2 N_{\mathrm{C}}}}\left[P P+M_{\mathrm{D}}\right] \gamma_{5} \phi_{\mathrm{D}}(x, b),  \tag{1}\\
& \int \frac{\mathrm{d}^{4} \omega}{(2 \pi)^{4}} \mathrm{e}^{\mathrm{i} k \omega}\langle 0| \bar{c}(0) s(\omega)\left|\mathrm{D}^{-}\right\rangle \\
= & -\frac{\mathrm{i}}{\sqrt{2 N_{\mathrm{C}}}}\left[\left(\not P+M_{\mathrm{D}}\right) \not \phi_{\mathrm{L}} \phi_{\mathrm{D}}^{\mathrm{L}}(x, b)\right. \\
& \left.+\left(P+M_{\mathrm{D}}\right) \not \not_{\mathrm{T}} \phi_{\mathrm{D}}^{\mathrm{T}}(x, b)\right] . \tag{2}
\end{align*}
$$

As for the $\mathrm{D}_{\mathrm{S}}^{-}\left(\mathrm{D}^{-}\right)$meson, we assume that $\phi_{\mathrm{D}}^{\mathrm{L}}=\phi_{\mathrm{D}}^{\mathrm{T}}=$ $\phi_{\mathrm{D}}$ in the heavy quark limit. Then the D meson wave function is decomposed in terms of spin structure as [14]

$$
\begin{equation*}
\Phi_{\mathrm{D}}(x, b)=-\frac{\mathrm{i}}{\sqrt{2 N_{\mathrm{C}}}}\left[P+M_{\mathrm{D}}\right] \gamma_{5} \phi_{\mathrm{D}}(x, b) \tag{3}
\end{equation*}
$$

where $\not P$ is the D meson's momentum, $M_{\mathrm{D}}$ is the mass of D and $\phi_{\mathrm{D}}$ is the Lorentz scalar distribution ampli-
the second model $\phi_{\mathrm{D}}^{\mathrm{MGEN}}$ has two parameters, while $\phi_{\mathrm{D}}^{\text {GEN }}$ and $\phi_{\mathrm{D}}^{\text {Huang }}$ are just $b$ independent. But we think the transverse momentum dependent part of the wave function is irrelevant here, so we set $b=0$ in these D meson distribution amplitudes [4]. Then $\phi_{\mathrm{D}}^{\mathrm{MGEN}}$ is the same as $\phi_{\mathrm{D}}^{\mathrm{GEN}}$. And we get five wave functions, which are all $b$ independent in Fig. 1.

Their normalization relation is

$$
\begin{equation*}
\int_{0}^{1} \phi_{\mathrm{D}}^{\mathrm{i}}(x, b=0) \mathrm{d} x=\frac{f_{\mathrm{D}}}{2 \sqrt{2 N_{\mathrm{C}}}}, \tag{10}
\end{equation*}
$$

where $N_{\mathrm{C}}=3$ is the color degree of freedom and $f_{\mathrm{D}}$ is the D meson decay constant.

As shown in Fig. 1, the five wave functions all have a small sharp, excepting their different shape. Besides the variable $x$, all of the functions have only one parameter, the $C_{\mathrm{D}}, \omega$ or $\Lambda_{\mathrm{D}}$. In the following, we
will study the uncertainties due to these wave functions and the parameters in them.

Fig. 1. D meson wave functions $\phi_{\mathrm{D}}^{\mathrm{i}}(\mathrm{i}=\mathrm{GEN}$, GN, Huang, KKQT, KLS).

In the SM, the Feynman diagram for pure-leptonic decays of $D_{S}^{-}\left(\mathrm{D}^{-}\right) \rightarrow \mathrm{l} \bar{v}$ is in Fig. 2. However, it is helically suppressed by $m_{1}^{2} / m_{\mathrm{W}}^{2}$, as we mentioned in Section 1. But the helicity suppression would be overcome if a photon were emitted from the charged particles [6]. We see that there are four charged particle lines in Fig. 2. So the radiative decays of $\mathrm{D}_{\mathrm{S}}^{-}\left(\mathrm{D}^{-}\right) \rightarrow \gamma \mathrm{l} \overline{\mathrm{v}}$ have four diagrams, such as Fig. 3.

Fig. 2. Feynman diagrams in the Standard Model for $D_{s}^{-} \rightarrow I \bar{v}$ decay.

However, the photon line is emitted from the internal charged line of W boson in Fig. 3(d), and there is a suppression factor of $m_{\mathrm{c}}^{2} / m_{\mathrm{W}}^{2}$ at this time. Compared with the process $\mathrm{D}_{\mathrm{S}}^{-}\left(\mathrm{D}^{-}\right) \rightarrow \mathrm{l} \bar{v}$, it can be neglected [8]. So, we get three decay amplitudes $\mathcal{H}_{\mathrm{a}}$, $\mathcal{H}_{\mathrm{b}}$ and $\mathcal{H}_{\mathrm{c}}$ for the photon radiating from the quarks, $\overline{\mathrm{c}}$ and l , which correspond to Fig. 3(a), (b) and (c),

$$
\begin{align*}
\mathcal{H}_{\mathrm{a}}= & -\mathrm{i} \sqrt{2} G_{\mathrm{F}} e V_{\mathrm{cs}} \bar{c}\left[Q_{\mathrm{c}} \not \phi_{\gamma} \frac{\not \gamma_{\gamma}-\not p_{\mathrm{c}}+m_{\mathrm{c}}}{\left(p_{\mathrm{c}} \cdot p_{\gamma}\right)} \gamma_{\mu} P_{\mathrm{L}}\right] \\
& \times s\left(\bar{l} \gamma^{\mu} P_{\mathrm{L}} v\right)  \tag{11}\\
\mathcal{H}_{\mathrm{b}}= & -\mathrm{i} \sqrt{2} G_{\mathrm{F}} e V_{\mathrm{cs}} \bar{c}\left[Q_{\mathrm{s}} P_{\mathrm{R}} \gamma_{\mu} \frac{\not p_{\mathrm{s}}-\not p_{\gamma}+m_{\mathrm{s}}}{\left(p_{\mathrm{s}} \cdot p_{\gamma}\right)} \not \phi_{\gamma}\right] \\
& \times s\left(\bar{l} \gamma^{\mu} P_{\mathrm{L}} v\right) \tag{12}
\end{align*}
$$

$$
\begin{align*}
\mathcal{H}_{\mathrm{c}}= & -\mathrm{i} \sqrt{2} G_{\mathrm{F}} e V_{\mathrm{cs}}\left(\bar{c} \gamma^{\mu} P_{\mathrm{L}} s\right) \\
& \times\left[\bar{l} \phi_{\gamma} \frac{\not p_{\gamma}+\not p_{1}+m_{1}}{\left(p_{1} \cdot p_{\gamma}\right)} \gamma_{\mu} P_{\mathrm{L}} v\right] . \tag{13}
\end{align*}
$$

We use the interpolating field techniques [17] that relate the hadronic matrix elements to the decay constants of the $\mathrm{D}_{\mathrm{S}}^{-}$mesons. The decay constant $f_{\mathrm{D}_{\mathrm{S}}^{-}}$for a charged pseudoscalar meson is defined by $\langle 0| \bar{c} \gamma^{\mu} \gamma_{5} s\left|\mathrm{D}_{\mathrm{S}}^{-}\right\rangle=\mathrm{i} f_{\mathrm{D}_{\mathrm{S}}^{-}} p_{\mathrm{D}_{\mathrm{S}}}^{\mu}[18]$.

Fig. 3. Feynman diagrams in the Standard Model for $D_{s}^{-} \rightarrow \gamma \overline{\mathrm{v}}$ decay.

After calculation and simplification, we get the whole decay amplitude for $D_{S}^{-}\left(D^{-}\right) \rightarrow \gamma l \bar{v}(l=e, \mu)$,

$$
\begin{align*}
\mathcal{A}= & \frac{\sqrt{2} e G_{\mathrm{F}} V_{\mathrm{cs}}}{6} f_{\mathrm{D}}\left[\left(\frac{1}{\left(p_{\mathrm{s}} \cdot p_{\gamma}\right)}-2 \frac{1}{\left(p_{\mathrm{c}} \cdot p_{\gamma}\right)}\right)\right. \\
& \times \mathrm{i} \epsilon_{\alpha \beta \mu \nu} p_{\gamma}^{\alpha} \epsilon_{\gamma}^{\beta} p_{\mathrm{B}}^{v}+\left(6-\frac{1}{\left(p_{\mathrm{s}} \cdot p_{\gamma}\right)}-2 \frac{1}{\left(p_{\mathrm{c}} \cdot p_{\gamma}\right)}\right) \\
& \left.\times\left(p_{\gamma \nu} \epsilon_{\gamma \mu}-p_{\gamma \mu} \epsilon_{\gamma \nu}\right) p_{\mathrm{D}_{\mathrm{S}}}\right]\left(\bar{l} \gamma^{\mu} P_{\mathrm{L}} v\right) \tag{14}
\end{align*}
$$

where we neglect all of the terms suppressed by $m_{1} / m_{\mathrm{c}}$.

Using the normalization relation of the wave function in Eq. (10), the decay amplitude is then

$$
\begin{align*}
\mathcal{A}= & \frac{\sqrt{2} e G_{\mathrm{F}} V_{\mathrm{cs}}}{6 P_{\mathrm{B}} \cdot p_{\gamma}} 2 \sqrt{2 N_{\mathrm{c}}}\left[\left(\int_{0}^{1} \frac{\phi(x)}{\left(p_{\mathrm{s}} \cdot p_{\gamma}\right)} \mathrm{d} x\right.\right. \\
& \left.-2 \int_{0}^{1} \frac{\phi(x)}{\left(p_{\mathrm{c}} \cdot p_{\gamma}\right)} \mathrm{d} x\right) \mathrm{i} \epsilon_{\alpha \beta \mu \nu} p_{\gamma}^{\alpha} \epsilon_{\gamma}^{\beta} p_{\mathrm{B}}^{\nu} \\
& +\left(6-\int_{0}^{1} \frac{\phi(x)}{\left(p_{\mathrm{s}} \cdot p_{\gamma}\right)} \mathrm{d} x-2 \int_{0}^{1} \frac{\phi(x)}{\left(p_{\mathrm{c}} \cdot p_{\gamma}\right)} \mathrm{d} x\right) \\
& \left.\times\left(p_{\gamma \nu} \epsilon_{\gamma \mu}-p_{\gamma \mu} \epsilon_{\gamma \nu}\right) p_{\mathrm{D}_{\mathrm{S}}}\right]\left(\bar{l} \gamma^{\mu} P_{\mathrm{L}} v\right) \tag{15}
\end{align*}
$$

From the definition of the wave function, we have $p_{\mathrm{s}}=(1-x) P_{\mathrm{D}_{\mathrm{S}}}, p_{\mathrm{c}}=x P_{\mathrm{D}_{\mathrm{S}}}$. Then we can get the decay amplitude,

$$
\begin{align*}
\mathcal{A}= & \frac{\sqrt{2} e G_{\mathrm{F}} V_{\mathrm{cs}}}{6 P_{\mathrm{B}} \cdot p_{\gamma}} 2 \sqrt{2 N_{\mathrm{c}}}\left[\left(\int_{0}^{1} \frac{\phi(x)}{(1-x)} \mathrm{d} x-2 \int_{0}^{1} \frac{\phi(x)}{x} \mathrm{~d} x\right)\right. \\
& \times \mathrm{i} \epsilon_{\alpha \beta \mu \nu} p_{\gamma}^{\alpha} \epsilon_{\gamma}^{\beta} P_{\mathrm{B}}^{v}+\left(6-\int_{0}^{1} \frac{\phi(x)}{(1-x)} \mathrm{d} x\right. \\
& \left.\left.-2 \int_{0}^{1} \frac{\phi(x)}{x} \mathrm{~d} x\right)\left(p_{\gamma \nu} \epsilon_{\gamma \mu}-p_{\gamma \mu} \epsilon_{\gamma \nu}\right) P_{\mathrm{D}_{\mathrm{S}}}\right]\left(\bar{l} \gamma^{\mu} P_{\mathrm{L}} v\right) . \tag{16}
\end{align*}
$$

Finally, the amplitude can be written simply as

$$
\begin{align*}
\mathcal{A}= & \frac{\sqrt{6} e C}{6}\left[C_{1} \mathrm{i}_{\alpha \beta \mu \nu} p_{\gamma}^{\alpha} \epsilon_{\gamma}^{\beta} p_{\mathrm{B}}^{\nu}+C_{2}\left(p_{\gamma \nu} \epsilon_{\gamma \mu}\right.\right. \\
& \left.\left.-p_{\gamma \mu} \epsilon_{\gamma \nu}\right) p_{\mathrm{D}_{\mathrm{S}}}\right]\left(\bar{l} \gamma^{\mu} P_{\mathrm{L}} v\right) \tag{17}
\end{align*}
$$

and the parameters in Eq. (17) are

$$
\begin{align*}
C & =2 \sqrt{2} G_{\mathrm{F}} V_{\mathrm{cs}} \alpha  \tag{18}\\
C_{1} & =\int_{0}^{1} \frac{\phi(x)}{(1-x)} \mathrm{d} x-2 \int_{0}^{1} \frac{\phi(x)}{x} \mathrm{~d} x  \tag{19}\\
C_{2} & =6-\int_{0}^{1} \frac{\phi(x)}{(1-x)} \mathrm{d} x-2 \int_{0}^{1} \frac{\phi(x)}{x} \mathrm{~d} x \tag{20}
\end{align*}
$$

After squaring the amplitudes, and then performing the phase space integration over one of the two Dalitz variables, we get the differential decay width versus the photon energy $E_{\gamma}$ [19],

$$
\begin{equation*}
\frac{\mathrm{d} \Gamma}{\mathrm{~d} E_{\gamma}}=\frac{6 C^{2}}{12 \pi}\left(C_{1}^{2}+C_{2}^{2}\right)\left(M_{\mathrm{D}_{\mathrm{S}}}-E_{\gamma}\right) E_{\gamma} \tag{21}
\end{equation*}
$$

Integrating the variable $E_{\gamma}$, we obtain the decay width,

$$
\begin{equation*}
\Gamma=\frac{M_{\mathrm{D}_{\mathrm{S}}}^{3} C^{2} \alpha}{(24 \pi)^{2}}\left(C_{1}^{2}+C_{2}^{2}\right) \tag{22}
\end{equation*}
$$

Finally, we obtain the branching ratio,

$$
\begin{equation*}
B_{\mathrm{r}}=\frac{\Gamma \cdot \tau_{\mathrm{D}_{\mathrm{S}}}}{\hbar} \tag{23}
\end{equation*}
$$

## 3 Numerical results

In the numerical calculations, we use the following input parameters $[9,10,19,20]$,

$$
\begin{aligned}
M_{\mathrm{D}_{\mathrm{S}}^{-}} & =1.97 \mathrm{GeV}, \quad\left|V_{\mathrm{cs}}\right|=0.974, \quad \alpha=1 / 137 \\
M_{\mathrm{D}^{-}} & =1.87 \mathrm{GeV}, \quad\left|V_{\mathrm{cd}}\right|=0.22, \quad \omega=0.4 \\
\hbar & =6.582122 \times 10^{-25}, \quad G_{\mathrm{F}}=1.66 \times 10^{-5} \mathrm{GeV}^{-2} \\
\tau_{\mathrm{D}^{-}} & =1.05 \times 10^{-12}, \quad f_{\mathrm{D}_{-}}=0.23 \mathrm{GeV}, \quad \Lambda_{\mathrm{D}}=0.75 \\
\tau_{\mathrm{D}_{\mathrm{S}}^{-}} & =0.5 \times 10^{-12}, \quad f_{\mathrm{D}_{\mathrm{S}}^{-}}=0.23 \mathrm{GeV} \\
\pi & =3.14159265359
\end{aligned}
$$

In Fig. 4, we show the differential decay width of $\mathrm{D}_{\mathrm{S}}^{-} \rightarrow \gamma \mathrm{l} \overline{\mathrm{v}}$ and $\mathrm{D}^{-} \rightarrow \gamma \mathrm{l} \bar{v}$ versus the photo energy $E_{\gamma}$, respectively. Obviously, different wave functions have the same shape. But the photo energy has a different peak value - it peaks in the range of 2.2 GeV to 2.8 GeV for $\mathrm{D}_{\mathrm{S}}^{-} \rightarrow \gamma \mathrm{l} \bar{v}$ and 1.0 GeV to 1.4 GeV for $\mathrm{D}^{-} \rightarrow \gamma \mathrm{l} \bar{v}$, respectively. The uncertainties here are from the style of D meson wave functions and their parameters. We show them in Table 1, Table 2 and Table 3. Table 1 contains all of the influences from the wave function style. Table 2 shows the uncertainty due to the parameters of the wave function. By calculation, we find that the influences of the parameters in wave function are very small. And we fit the parameters for the wave functions. Table 3 shows the branching ratios of the different wave functions. From the table, we also see that different wave functions give different branching ratios. From Fig. 4, we find that the line of $\phi_{\mathrm{D}}^{\mathrm{KKQT}}$ is higher and the $\phi_{\mathrm{D}}^{\mathrm{KLS}}$ is lower.

Fig. 4. Differential decay of $\mathrm{D}_{\mathrm{S}}^{-} \rightarrow \gamma \mathrm{l} \bar{v}$ and $\mathrm{D}^{-} \rightarrow \gamma \mathrm{l} \bar{v}$ versus the photo energy $E_{\gamma}$.

Table 1. Comparison of influences from different wave functions. It can be found in Eq. (17-20) that the influences of wave functions are all in $C_{1}$ and $C_{2}$. And obviously, the value variety of the $\left(C_{1}^{2}+C_{2}^{2}\right)$ is big. It is about 24 to 42 .

| wave function | GEN | GN | KKQT | KLS | Huang |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\left(C_{1}^{2}+C_{2}^{2}\right) \mathrm{D}_{\mathrm{S}}^{-} \rightarrow \gamma \mathrm{l} \bar{v}$ | 30.7426 | 28.4296 | 41.5979 | 24.0445 | 30.1052 |
| $\left(C_{1}^{2}+C_{2}^{2}\right) \mathrm{D}^{-} \rightarrow \gamma \mathrm{l} \bar{v}$ | 30.7426 | 28.4446 | 41.9284 | 24.5063 | 30.0337 |

Table 2. Comparison of influences from different parameters of the wave functions. We find that the effects of parameters on the wave functions are small. The biggest influence is from $\Lambda_{\mathrm{D}}$ in $\phi^{\mathrm{KKQT}}$, and it is only of the order of $10^{-6}$.

| wave function | parameter | $B_{r}\left(\mathrm{D}_{\mathrm{S}}^{-}\right) \times 10^{-5}$ | $B_{r}\left(\mathrm{D}^{-}\right) \times 10^{-6}$ |
| :---: | :---: | :---: | :---: |

| $B_{r}\left(\mathrm{D}^{-} \rightarrow \gamma \mathrm{l} \bar{v}\right) \times 10^{-6}$ | 1.157828 | 1.069288 | 1.576725 | 0.953498 | 1.132268 | 4.6 |

The other three $\phi_{\mathrm{D}}^{\mathrm{GEN}}, \phi_{\mathrm{D}}^{\text {Huang }}$ and $\phi_{\mathrm{D}}^{\mathrm{GN}}$ are closer compared with the other wave functions. So, we conclude that these three wave functions are more fit for the pure-leptonic radiative decay of $\mathrm{D}_{\mathrm{S}}^{-}\left(\mathrm{D}^{-}\right) \rightarrow \gamma \mathrm{l} \overline{\mathrm{v}}$. Of course, they will be measured by future experiments, such as BESIII.

## 4 Summary

In this paper, we find that the branching ratios are sensitive to the type of wave function. We show that the decay branching ratios in the SM for $\mathrm{D}_{\mathrm{S}}^{-} \rightarrow \gamma \mathrm{l} \bar{v}$
$(\mathrm{l}=\mathrm{e}, \mu)$ is of the order of $10^{-5}$ and for $\mathrm{D}^{-} \rightarrow \gamma \mathrm{l} \bar{\nu}$ $(l=e, \mu)$ of $10^{-6}$. The different type of wave functions and different input parameters affect the size of the decay branching ratios but not the shape of the photon energy spectrum. These decay channels are useful to determine the decay constants $f_{\mathrm{D}}$ and or D meson wave function. After calculation, it is found that our leading order results are the same order as other approaches, but a little smaller than the sum rule approaches [21]. Such a branching ratio for the radiative leptonic decays can be measured in future BESIII experiments.
