# **Cosmological constraints on the background dynamics of a two-field nonsingular bounce model**

Kang Song Ri<sup>†</sup><sup>D</sup> Sin Chol Hwang Hyon Chol Ri

Department of Physics, Kim Il Sung University, Ryongnam Dong, Taesong District Pyongyang, Democratic People's Republic of Korea

**Abstract:** In this study, we consider a nonsingular two-field bounce scenario with non-minimal kinetic coupling between two scalar fields. We derive constraints on the model parameters from the finiteness of the physical quantities at the classical level and from the relation between the late-time accelerated expansion and particle production up to the bounce phase. We then determine the allowed parameter space for the model.

**Keywords:** bounce universe, parameter space

## **I. INTRODUCTION**

Theinflationary scenario [[1\]](#page-6-0) has become the standard paradigm for the early universe. It solves many of the theoretical problems of Big Bang cosmology and explains the observed cosmological perturbations[[2\]](#page-6-1). However, the initial singularity problem[[3\]](#page-6-2) of the Big Bang cosmology remains unsolved under the inflationary paradigm [[4](#page-6-3), [5\]](#page-6-4), i.e., ever expanding cosmologies must be past incomplete. This motivates us to explore alternatives to the inflationary cosmol[og](#page-6-5)y.

A bouncing universe  $[6, 7]$  $[6, 7]$  $[6, 7]$  (for reviews, see  $[8-10]$  $[8-10]$  $[8-10]$ ), an alternative to the inflationary cosmology, offers a potential solution to the initial singularity problem. However, the bounce scenario also faces several theoretically and phenomenologically challenging issues. Firstly, a cosmic nonsingular bounce can only occur when the null energy condition is violated, which typically gives rise to a ghost instability. This issue can be circumvented by introduci[ng a](#page-6-9) [ne](#page-6-10)w kind of m[atte](#page-6-11)r field, such as g[hos](#page-6-12)t condensates [\[11,](#page-6-9) [12](#page-6-10)[\], G](#page-6-13)alileons [[13](#page-6-11)], quintom fields [\[14\]](#page-6-12), or Lee-Wick fields [\[15\]](#page-6-13). Secondly, a contracting phase of a bouncing cosmology is generally unstable under the growth o[f an](#page-6-14)isotropies, which is known as the BKL instability [\[16\]](#page-6-14). The solution to this problem is to introduce a scalar field with a steep and negative-valued potential that do[mi](#page-6-15)n[ate](#page-6-16)s over anisotropies during the contracting phase [\[17,](#page-6-15) [18](#page-6-16)]. During this ekpyrotic contracting phase, homogeneity, isotropy, and flatness can be achieved after the scale factor of the universe shrinks by just a few efolds, even if the i[niti](#page-6-17)[al s](#page-6-18)tate is highly non-homogeneous and non-isotropic [[19](#page-6-17), [20](#page-6-18)].

Another important issue with bounce models is that it

cludes a ekpyrotic phase was constructed within  $N = 1$ is relatively difficult to obtain them based on the low-energy effective field theory of string theory or quantum gravity. In [\[21\]](#page-6-19), a nonsingular bounce model based on a ghost condensate and a Galileon field theory that in-supergravity.In [[22](#page-6-20)], this model was improved into a much simpler model where the nonsingular bounce is supported by a scalar field with a pure ghost condensate kinetic term and ekpyrotic potential.

To generate nearly scale-invariant curvature perturbations with small non-Gaussianities, in [\[23\]](#page-6-21), the model propose[d i](#page-6-22)n [\[22\]](#page-6-20) was combined with the entropic mechanism[[24](#page-6-22)] where the entropy field is couple[d to](#page-6-23) [th](#page-6-24)e bo[unce](#page-6-25) field by a non-minimal kinetic coupling [\[25,](#page-6-23) [26](#page-6-24)]. In [\[27\]](#page-6-25), the possibility of incorporating the late-time accelerated expansion was explored, and two phenomenological constraints were obtained by comparing the ampl[it](#page-6-1)ude o[f cu](#page-6-26)rvature perturbations with the observed value [[2](#page-6-1)]. In [\[28\]](#page-6-26), the amount of generated particles up to the bounce phase was evaluated based on detailed investigation of the background evolution during the bounce phase.

All pre[vio](#page-6-20)[us s](#page-6-21)[tud](#page-6-25)ies indicated that the models con-sidered in [[22](#page-6-20), [23](#page-6-21), [27\]](#page-6-25) can be not only theoretically promising but also phenomenologically viable. However, it is unpreferable if the model suffers such severe constraints that the allowed parameter space has a much smaller volume than other models for the early universe.

In this paper, we aim to derive theoretical and phenomenological constrai[nts](#page-6-20) [on](#page-6-21) [the](#page-6-25) nonsingular bounce scenario considered in [[22](#page-6-20), [23](#page-6-21), [27](#page-6-25)] to investigate the allowed parameter space. Concretely, one constraint is obtained by requiring the model not to have a singularity at

the background level, and the other is derived by using the relation between the energy density of the particles created by the classical backgrounds and the late-time accelerated expansion [\[27\]](#page-6-25). We then determine the allowed parameters of the model by combining these with the constraints obtained in [\[27\]](#page-6-25).

Following [[28](#page-6-26)], we use the Planck units with  $\hbar = c =$  $8\pi G_N = 1$  (where  $G_N$  is Newton's gravitational constant) and take the sign of the metric to be  $(-,+,+,+)$  in this paper.

### **II. LAGRANGIAN**

The model that we consider consists of two kinetically-coupled scalar fields: a bounce field  $\phi$  that violates the Null Energy Condition for a short period and induces the cosmic bounce and an entropic field *χ* that is responsible for generating nearly scale-invariant scalar perturbations. The corresponding Lagrangian is given by [\[22,](#page-6-20) [23](#page-6-21),  $\left[ 27\right] ^{1)}$  $\left[ 27\right] ^{1)}$  $\left[ 27\right] ^{1)}$ 

$$
\mathcal{L} = \frac{R}{2} - \frac{1}{2} K(\phi) \partial_{\mu} \phi \partial^{\mu} \phi + \frac{1}{4} Q(\phi) (\partial_{\mu} \phi \partial^{\mu} \phi)^{2}
$$

$$
- V(\phi) - \frac{1}{2} \Omega(\phi)^{2} \partial_{\mu} \chi \partial^{\mu} \chi,
$$
(1)

where *R* is the Ricci scalar, and

$$
K(\phi) = 1 - \frac{2}{(1 + \frac{1}{2}\phi^2)^2}, \quad Q(\phi) = \frac{q}{(1 + \frac{1}{2}\phi^2)^2}.
$$
 (2)

The form of  $\Omega(\phi)$  should be chosen such that nearly scale-invariant entropic perturbations are generated during the ekpyrotic contracting phase. A simple such form is [\[25,](#page-6-23) [30](#page-6-27)]

$$
\Omega(\phi) = \exp\left(\frac{b}{2}\phi\right),\tag{3}
$$

 $b \approx 1.02\lambda$ ; see, e.g., [\[23\]](#page-6-21)) so that the scalar spectral index  $n<sub>s</sub>$  falls in the range [of](#page-6-21)  $(0.95, 0.97)$ . However, this simple where the parameter *b* is slightly larger than  $\lambda$  (i.e., form leads to an extremely inefficient conversion process from the entropic perturbation into the curvature fluctuation after the ekpyrotic contracting phase, due to the significant scalar curvature in the field space [\[31\]](#page-6-28). The curvature perturbation then has a small ampl[itud](#page-6-28)e and large non-Gaussianities, which is clearly in contradiction with observations [[31](#page-6-28)]. For this reason, it is necessary to flatten the field spa[ce](#page-6-28) metric after the ekpyrotic phase. As

the ekpyrotic phase contracting ends at around  $\phi =$  $-\sqrt{2(\sqrt{2}-1)} \approx -0.9$  [\[28\]](#page-6-26), we take the function  $\Omega(\phi)$  as

$$
\Omega(\phi) = \exp\left(\frac{b}{2}(x+1)\frac{\frac{2}{\pi}\arctan(-100(x+1))+1}{2}\right),\qquad(4)
$$

we assume that the scalar field  $\phi$  evolves from  $-\infty$  in the form of  $Ω(φ)$ . see [Fig. 1](#page-2-0) for co[mp](#page-6-26)arison of  $(3)$  and  $(4)$ . As in  $[28]$ , here, positive direction without loss of [gen](#page-6-20)[eral](#page-6-21)i[ty.](#page-6-25) [In](#page-6-29) Section IV, we give res[ults](#page-6-26) for particle creation significantly different from in[[28](#page-6-26)], which is due to the change of the

The scalar potential is given by [[22](#page-6-20), [23,](#page-6-21) [27,](#page-6-25) [32](#page-6-29)]

$$
V(\phi) = V_{\text{DE}} - V_0 \cdot \text{sech}(\lambda \phi),\tag{5}
$$

where  $V_{DE} > 0$ , which is almost equal to the dark energy [ach](#page-6-15)i[eve](#page-6-30)d by setting the parameter  $\lambda$  to be greater than  $\sqrt{6}$ density, is intro[duc](#page-6-25)e[d t](#page-6-29)o account for the late-time accelerated expansion [[27](#page-6-25), [32](#page-6-29)]. This parameter is so small that it can be neglected before the late-time accelerated expandi[ng](#page-6-15) [pha](#page-6-30)se. As mentioned in the Introduction, the potential (5) should be so steep that the unwanted anisotropies are sufficiently diluted before the bounce. This is [[17](#page-6-15), [33](#page-6-30)].

# **III. BACKGROUND DYNAMICS AND [C](#page-6-26)LASSICAL SINGULARITY**

a scale factor  $a(t)$ . The background equations of motion We take the background metric to be a flat Friedmann-Le[ma](#page-6-21)î[tre-](#page-6-26)Robertson-Walker (FLRW) universe with are then [[23](#page-6-21), [28](#page-6-26)]

$$
3H^{2} = \frac{1}{2}K(\phi)\dot{\phi}^{2} + \frac{3}{4}Q(\phi)\dot{\phi}^{4} + V(\phi),
$$
\n(6)

$$
\dot{H} = -\frac{1}{2}K(\phi)\dot{\phi}^2 - \frac{1}{2}Q(\phi)\dot{\phi}^4,\tag{7}
$$

$$
0 = (K(\phi) + 3Q(\phi)\dot{\phi}^2)\ddot{\phi} + 3H\dot{\phi}(K(\phi) + Q(\phi)\dot{\phi}^2) + V_{,\phi} + \left(\frac{1}{2}K_{,\phi} + \frac{3}{4}Q_{,\phi}\dot{\phi}^2\right)\dot{\phi}^2 - \frac{1}{2}\frac{\Omega_{,\phi}}{\Omega}\dot{\chi}^2,
$$
(8)

<sup>1)</sup> In most of the nonsingul[ar bo](#page-6-26)unce models including the one discussed in this work, the speed of sound squared of primordial scalar perturbations becomes negative around the bounce point, leading to gradient instabilities. This issue can be resolved by adding the Degenerate Higher-Order Scalar-Tensor (DHOST) terms [\[29\]](#page-6-31). Since inclusion of these additi[ona](#page-6-26)l higher-order derivative terms do not alter the background dynamics, the analysis below is still valid even including the DHOST terms.

<span id="page-2-0"></span>

**Fig. 1.** (color online) Log-plot of  $\Omega(\phi)$  given by (3) and (4) for  $b = 1.02 \sqrt{20}$ .

$$
0 = \ddot{\chi} + \left(3H + 2\frac{\dot{\Omega}}{\Omega}\right)\dot{\chi},\tag{9}
$$

where the Hubble parameter *H* is given by  $H \equiv \dot{a}/a$ , and cosmic time  $t$ ; the subscript,  $\phi$  denotes the derivative with the over-dot refers to the derivative with respect to the respect to *ϕ*.

the null energy condition can occur only when  $K(\phi)$  becomes negative, or  $|\phi| \le \sqrt{2(\sqrt{2}-1)} \approx 0.9$ . At this time,  $Q(\phi)$  that controls the magnitude of the higher derivative by the period when  $K(\phi)$  has negative value. One can readily see from (2) and (7) that violation of term becomes large so that the ghost condensation can occur [\[11,](#page-6-9) [21,](#page-6-19) [22](#page-6-20), [28\]](#page-6-26). Here, we define the bounce phase

Outside of the bounce phase, the Lagrangian (1) is effectively reduced to the canonical form, and the back[grou](#page-6-25)nd dynamics in this case were analysed in detail in [[27\]](#page-6-25). In summary, the universe undergoes the ekpyrotic contracting phase, bounce phase, kinetic energy dominated expanding phase, and finally the standard Big Bang cosmology, which is [a](#page-6-20) t[ypi](#page-6-21)[cal](#page-6-25) e[vo](#page-6-26)lution [of the](#page-2-1) nonsingular bounce scenario [[22](#page-6-20), [23,](#page-6-21) [27,](#page-6-25) [28](#page-6-26)], see [Fig. 2.](#page-2-1)

[ $28$ ] that when  $qV_0$  has a large value, the Hubble paramet-Note that it is not clear whether this means of evolution of the bouncing universe holds true for any values of t[he](#page-6-26) parameters in the model (1). It was indeed reported in er decreases rapidly after the bounce phase so that it can become a negative infinity in a finite time, which leads to a new kind of classical singularity. Hence, we would like to derive a necessary condition for this sort of singularity not to occur.

It is obvious that this classical singularity will certainly appear if the Hubble parameter takes a negative value at the end of the bounce phase. As the Hubble parameter is negative at the beginning of the bounce phase, one can immediately see that the necessary condition is

$$
\int_{t_{B-}}^{t_{B+}} dt \, \dot{H} > 0, \tag{10}
$$

<span id="page-2-1"></span>

given by  $\lambda = \sqrt{10}$ ,  $q = 10^8$ , and  $V_0 = 2 \times 10^{-10}$ . The horizontal **Fig. 2.** (color online) Plot of *H* for the model parameters axis denotes  $\phi$ . The scalar field  $\phi$  evolves in the positive direction. The universe undergoes ekpyrotic contracting phase, bounce phase, and kinetic energy-dominated expanding phase. The final Big Bang standard evolution is not depicted. The plot is insensitive to the initial condition due to the attractor nature of the ekpyrotic solution [\[34](#page-6-32), [35\]](#page-6-33).

where  $t_{B-}$  and  $t_{B+}$  refer to the cosmic time at the beginning and end of the bounce phase, respectively. In addition, it holds that during the bounce phase [\[28\]](#page-6-26),

$$
\dot{\phi}^2 \simeq \frac{-K(\phi) + \sqrt{K^2(\phi) - 12Q(\phi)V(\phi)}}{3Q(\phi)}.\tag{11}
$$

Therefore, we find that the necessary condition becomes

$$
\int_{\phi_{B-}}^{\phi_{B+}} d\phi \sqrt{\frac{-K(\phi) + \sqrt{K^2(\phi) - 12Q(\phi)V(\phi)}}{Q(\phi)}}
$$
  
 
$$
\times \left(-2K(\phi) - \sqrt{K^2(\phi) - 12Q(\phi)V(\phi)}\right) > 0, \qquad (12)
$$

where  $\phi_{B-} = -\sqrt{2(\sqrt{2}-1)}$  and  $\phi_{B+} = +\sqrt{2(\sqrt{2}-1)}$  rep-*V* are even functions and  $1 \le Q(\phi)/q \le 2$  for  $\phi_{B-} \le$  $\phi \leq \phi_{B+}$ , the above necessary condition is reduced into a resent the values of  $\phi$  at the beginning and end of the bounce phase, respectively. Using the fact that *K*, *Q,* and simpler form, namely,

$$
\int_0^{\phi_{B+}} d\phi \sqrt{|K(\phi)| + P(\phi)} \left(2\sqrt{2}|K(\phi)| - P(\phi)\right) > 0,\qquad(13)
$$

where

$$
P(\phi) \equiv \sqrt{K^2(\phi) - 12Q(\phi)V(\phi)}.
$$
 (14)

We then proceed as follows:

115103-3

$$
(13) \Longrightarrow 2\sqrt{2} \int_0^{\phi_{B+}} d\phi |K| \sqrt{|K|+P} > \int_0^{\phi_{B+}} d\phi P \sqrt{|K|+P}
$$
  
\n
$$
\Longrightarrow 2\sqrt{2} \int_0^{\phi_{B+}} d\phi \left( |K|^{3/2} + |K| \sqrt{P} \right) > \int_0^{\phi_{B+}} d\phi P^{3/2}
$$
  
\n
$$
\Longrightarrow 4\sqrt{2} \int_0^{\phi_{B+}} d\phi |K|^{3/2} + 2\sqrt{2}(12qV_0)^{\frac{1}{4}} \int_0^{\phi_{B+}} \frac{d\phi}{\cosh^{\frac{1}{4}} \lambda \phi}
$$
  
\n
$$
> (12qV_0)^{\frac{3}{4}} \int_0^{\phi_{B+}} \frac{d\phi}{\cosh^{\frac{3}{4}} \lambda \phi}
$$
  
\n
$$
\Longrightarrow 4\sqrt{2}\lambda + 10\sqrt{2}(12qV_0)^{\frac{1}{4}} > \frac{3}{2}(12qV_0)^{\frac{3}{4}},
$$
\n(15)

where in the last line, we used

$$
\lambda \int_0^{\phi_{B+}} \frac{\mathrm{d} \phi}{\cosh^{\frac{1}{4}} \lambda \phi} < 5, \quad \lambda \int_0^{\phi_{B+}} \frac{\mathrm{d} \phi}{\cosh^{\frac{3}{4}} \lambda \phi} > \frac{3}{2},
$$

which can be verified numerically.

Equation (15) sets a *λ*-dependent upper bound on  $qV_0$ . For instance, one can find that  $qV_0 \le 16.2$  when  $\lambda = \sqrt{20}$ ; otherwise, the di[vergenc](#page-3-0)e of the Hubble parameter will surely appear (see [Fig. 3\)](#page-3-0).

# **IV. PARTICLE PRODUCTION AND LATE-TIME ACCELERATED EXPANSION**

Particle production [in](#page-6-26) [non](#page-6-34)s[ing](#page-6-35)ular bounce scenarios has been discussed in[[28](#page-6-26), [36](#page-6-34), [37\]](#page-6-35), where it was shown that, during the ekpyrotic contracting and bounce phases, particles are generated enough to reheat the universe. Meanwhile, the amount of particle production up to the bounce phase should not exceed a certain bound for the nonsingular bounce scenario, su[ch a](#page-6-25)s that given by (1), to be consistent with the currently observed accelerated expansion of the universe, namely [[27](#page-6-25)],

$$
\frac{\sqrt{\frac{\rho_{m0}}{\rho_0}}}{1+\sqrt{1+\frac{\rho_{m0}}{\rho_0}}} < \left(\frac{\rho_{CC}}{2\lambda V_0}e^{\lambda\phi_{B+}}\right)^{\frac{1-w_m}{\lambda}}\sqrt{\frac{3}{8}},\tag{16}
$$

or

$$
\frac{\lambda}{1 - w_m} \sqrt{\frac{3}{2}} \log \frac{\rho_{m0}}{\rho_0} < \phi_{B+} \lambda + \log \frac{\rho_{CC}}{2\lambda V_0},\tag{17}
$$

where  $\rho_{m0}$  and  $\rho_0$  refer to the energy density of matter/radiation with equation of state  $w_m$  and background at the end of the bounce phase, respectively, and  $\rho_{CC}$  represents 10−<sup>120</sup> in Planck units. Obviously, we can obtain a conthe observed dark energy density, which is of the order straint on the bounce scenario from (17), once the lower bound of energy density of the generated particles is expressed in terms of the model parameters.

ier mode  $v_k$  of  $v \equiv a\Omega(\phi)\chi$ , which is given by Hence, we would like to estimate the lower [bou](#page-6-26)nd of energy density of *χ*-particles generated up to the bounce phase. The whole procedure is similar to that in [\[28\]](#page-6-26). The first step is to solve the differential equation for the Four-

$$
v_k'' + (k^2 - \mu^2(\eta)) v_k = 0, \quad \mu^2(\eta) \equiv \mathcal{H}^2 + \mathcal{H}' + \frac{\Omega''}{\Omega} + 2\mathcal{H}\frac{\Omega'}{\Omega},
$$
\n(18)

conform[al t](#page-6-26)ime *η* defined by  $d\eta = a^{-1}dt$ . Note that the contribution of  $\Omega(\phi)$ -related terms to  $\mu^2(\eta)$  becomes neg-casein [[28](#page-6-26)], where  $\Omega(\phi)$ -related terms played a major [[28](#page-6-26), [36](#page-6-34), [37\]](#page-6-35), we assume the initial conditions for  $v_k$  corwhere the prime denotes the derivative with respect to the l[igi](#page-6-26)b[le f](#page-6-34)[rom](#page-6-35) the bounce phase, which is in contrast to the role in particle creation during the bounce phase. As in responding to a Bunch-Davies vacuum state, i.e.,

<span id="page-3-0"></span>

**Fig. 3.** (color online) Plots showing divergence of the Hubble parameter *H* for the model parameters given by  $\lambda = \sqrt{20}$ ,  $q = 10^8$ , and  $V_0 = 1.7 \times 10^{-7}$ . The left panel shows the evolution of *H* according to the cosmic time *t*, while in the right panel, the horizontal axis denotes *ϕ*. As mentioned before, the form of these plots does not depend on the initial conditions.

$$
\lim_{\eta \to -\infty} v_k = \frac{e^{-ik\eta}}{\sqrt{2k}}.
$$
\n(19)

As can be seen in [Fig. 4](#page-4-0),  $\mu^2(\eta)$  during the ekpyrotic and kinetic phase is much less than during the bounce phase. This implies that the solution of (18) during these phases is effectively given by a plane wave, namely,

$$
\nu_k \simeq \frac{\mathrm{e}^{-\mathrm{i}k(\eta-\eta_B-)}}{\sqrt{2k}}, \quad \eta \le \eta_{B-}, \tag{20}
$$

$$
v_k \simeq \frac{1}{\sqrt{2k}} \left( \alpha_k e^{-ik(\eta - \eta_{B+})} + \beta_k e^{+ik(\eta - \eta_{B+})} \right), \quad \eta \ge \eta_{B+},
$$
\n(21)

where  $\eta_{B-}$  and  $\eta_{B+}$  denote the conformal time at the becall that  $\alpha_k$  and  $\beta_k$  are the so-called Bogolyubov coefficients, and  $n_k = |\beta_k|^2$  gives the number density of gener-Bogolyubov coefficient  $\beta_k$  is determined, we can comginning and end of the bounce phase, respectively. Reated particles with comoving wave number *k*. Once the pute the energy density of the generated particles via [\[36\]](#page-6-34)

$$
\rho_{m0} = \frac{1}{2\pi^2} \int_0^\infty \mathrm{d}k \, k^3 |\beta_k|^2. \tag{22}
$$

Determining  $\beta_k$  requires us to solve (18) during the  $\mu^2(\eta)$  takes the complicated form in this phase (see, e.g., which contains only the logarithm of  $\rho_{m0}$ , we only need to estimate the order of  $\rho_{m0}$ . To this end,  $\mu^2(\eta)$  during the bouncephase as in  $[28]$  $[28]$  $[28]$ , which is non-trivial because [Fig. 4\)](#page-4-0). As our aim is just to use the inequality (17), bounce phase can be approximated by a certain constant value, namely,

$$
\mu^2(\eta) \simeq \Lambda^2,\tag{23}
$$

where  $\Lambda$  is an order one fraction of  $\mu_{\text{max}} =$ 

<span id="page-4-0"></span>

Fig. 4. (color online) Plot of  $\mu^2$  for the model parameters given by  $\lambda = 3\sqrt{20}$ ,  $q = 10^8$ , and  $V_0 = 2 \times 10^{-10}$ . The horizontal axis denotes *ϕ*.

 $\max_{\eta_B \leq \eta \leq \eta_B^+} |\mu(\eta)|$ . It is now simple to compute the Bogolyubov coefficient  $\beta_k$ , and hence, the energy density  $\rho_{m0}$  becomes

$$
\rho_{m0} \simeq \frac{1}{8\pi^2} \int_0^{\Lambda} dk \, k^3 \left| \sqrt{\frac{\Lambda^2}{k^2} - 1} - \frac{1}{\sqrt{\frac{\Lambda^2}{k^2} - 1}} \right|^2 \sinh^2(T \sqrt{\Lambda^2 - k^2}) + \frac{1}{8\pi^2} \int_{\Lambda}^{+\infty} dk \, k^3 \left| \sqrt{1 - \frac{\Lambda^2}{k^2}} - \frac{1}{\sqrt{1 - \frac{\Lambda^2}{k^2}}} \right|^2
$$
  
× sin<sup>2</sup>(T  $\sqrt{k^2 - \Lambda^2}$ ), (24)

where  $T = \eta_{B+} - \eta_{B-}$  is the duration of the bounce phase. gence disappears for smooth function  $\mu^2(\eta)$  [\[28,](#page-6-26) [38](#page-6-36)]. We therefore assume that there is an ultraviolet cutoff  $k_{\text{max}}$ . In fact, as shown explicitly in [[28](#page-6-26)], we can set  $k_{\text{max}}$  to  $3\mu_{\text{max}}$ ;  $k \ge 3\mu_{\text{max}}$  provide a minor contribution to  $\rho_{m0}$ . After a Obviously, the second integral in the above expression logarithmically diverges for large *k*, which has its origin in the approximation (23). Namely, this ultraviolet diverthe produced particles with comoving wave number change in variables, we get

$$
\frac{8\pi^2}{\Lambda^4} \rho_{m0} \simeq \int_0^1 ds \, s \left| 2s - \frac{1}{s} \right|^2 \sinh^2(\Lambda T s) + \int_0^3 \frac{ds}{s} \sin^2(\Lambda T s). \tag{25}
$$

One can readily see that the second integral is  $\mathcal{O}(1)$ , Λ*T* . while the first one has an exponential relationship with

Now, we only have to express  $\mu_{\text{max}}$  and *T* in terms of  $\dot{\phi} \sim 1/\sqrt{q}$  up to an order one factor during the bounce the model parameters. It follows from (6) that we have phase; therefore, the duration *T* of the bounce phase is up to an order one constant (cf., Eq. (24) in [[28](#page-6-26)])

$$
T \simeq \int_{\phi_{B-}}^{\phi_{B+}} \frac{\mathrm{d}\phi}{\dot{\phi}} \sim \sqrt{q},\tag{26}
$$

have  $\mu^2(\eta) \simeq \mathcal{H}' + \mathcal{H}^2$ , which can be estimated by using  $\mathscr{H}^2 \ll \mathscr{H}' \lesssim \frac{1}{96}$  $\overline{9q}$  [\[28\]](#page-6-26). It follows that up to order one conwhere we have used the fact that the change of the scale factor *a* during the bounce phase is negligible. Meanwhile, as mentioned before, during the bounce phase, we stants,

$$
\mu_{\max} \sim \Lambda \sim \frac{1}{\sqrt{q}}.\tag{27}
$$

Collecting the results above, we find that Λ*T* is order one, and therefore,

$$
\rho_{m0} \sim \frac{1}{8\pi^2 q^2},\qquad(28)
$$

up to an order one factor (cf., Eq.  $(46)$  in [\[28\]](#page-6-26), where  $\rho_{m0}$ depends on both *q* and *b*). The dependence of  $\rho_{m0}$  only on *q* among the model parameters is obvious; most particle creation by classical backgrounds occurs during the bounce phase, whose background dynamics basically depend on *q*.

Moreover,  $\rho_0$  is given by  $\rho_0 = 3H_{B+}^2$ , where  $H_{B+}$ , the order one fraction of  $1/\sqrt{q}$  [\[28\]](#page-6-26). Combining this with Hubble parameter at the end of the bounce phase, is an (17) and (28), we get a constraint

$$
\frac{\lambda}{2}\log q + \lambda + \log \frac{\rho_{CC}}{2\lambda V_0} > 0,\tag{29}
$$

particles have the equation of state  $w_m = 1/3$  and ignore where we consider the fact that most of the created some order one factors.

## **V. PARAMETER SPACE**

The two constraints we derived in the previous sections can be used in determining the parameter space for the nonsingular bounce scenario (1), in combination with other constraints already available in literature:

$$
V_0 \le 10^{-4},\tag{30a}
$$

$$
\sqrt{6} < \lambda \leq 38,\tag{30b}
$$

$$
\frac{\left(\frac{\lambda^2}{2} - 3\right)\cosh\left(\sqrt{2(\sqrt{2} - 1)}\lambda - 2\right)}{\left(\frac{\lambda^2}{2} - 1\right)^2} \lesssim 10^7 \mathcal{F}^2 V_0,
$$
\n(30c)

where  $\mathscr F$ , an amplification factor of the entropy perturbations across the bounce phase, is at most  $\mathcal{O}(10^4)$  [[23](#page-6-21)]. The for the model parameters  $q$ ,  $V_0$ , and  $\lambda$ ; the other ones, *b* and  $V_{DE}$ , are fixed in terms of  $\lambda$  and observations, as menfirst constraint comes from the fact that we are using the low-energy effective field theory des[cri](#page-6-20)ption and have to suppress any quantum gravity effect [[22](#page-6-20)]. The second and last constraints are due to suppressing the ani[sot](#page-6-37)ropic stresses during the ekpyrotic contracting phase [\[39\]](#page-6-37) and having the amplitude of the curvature perturbations in agreement wit[h t](#page-6-25)he observations (see Eq. (4.26) and (4.27) in Ref. [\[27\]](#page-6-25)). Note that all of these constraints are tioned before.

from  $\sqrt{6}$  to 7; for instance,  $\lambda = \sqrt{20}$ , which is typically the allowed range of parameters  $q$  and  $V_0$ . For instance,  $q$ and *V*<sub>0</sub> can vary by 12 [∼](#page-6-38) 13 orders of magnitude for  $\lambda = 32$ . This is indeed a large space; for instance, under 5 ∼ 7 orders of magnitude. This implies that the nonsinWe plot the parameter space for the model (1) [de](#page-5-0)[ter](#page-5-0)mined by the constraints  $(15)$ ,  $(29)$ , and  $(30)$  (see [Fig.](#page-5-0) [5\)](#page-5-0). One can clearly se[e t](#page-6-20)h[at t](#page-6-21)[he l](#page-6-25)ower bound of *λ* is lifted used in the literature [[22](#page-6-20), [23,](#page-6-21) [27\]](#page-6-25), is not allowed. In addition, it is evident that the greater the value of *λ*, the larger and  $V_0$  can vary by  $12 \sim 13$  orders of magnitude for minimal warm inflation [\[40\]](#page-6-38), the parameters can vary by gular bounce scenario (1) is preferable for the large values of *λ*.

<span id="page-5-0"></span>

**Fig. 5.** (color online) Allowed space for the model parameters *q*,  $V_0$ , and  $\lambda$ . Two dimensional space for *q* and  $V_0$  is plotted for various values of  $\lambda$  in the left figure, while the total three dimensional space is plotted in the right figure. The left figure shows that  $\lambda \le 7$  is not allowed.

#### **VI. CONCLUSIONS**

In this study, we derived two constraints (15) and (29): one from the possible appearance of the singularity in background evolution and the other one from the relation between particle creation and late-time accelerated expansion. Combining these with the already known constraints, we determined the allowed parameter space for

the nonsingular bounce scenario.

We emphasize that there can be other constraints; for instance, non-Gaussianity of the curvature perturbation may put a severe constraint on the model. For this, one must investigate the conversion of entropy perturbations into curvature perturbations in detail, which we plan to address in future work.
