Abstract: We study the pole trajectory of the recently established subthreshold negative-parity nucleon pole, namely the $N^*(920)$, with varying pion masses in the scheme of linear σ model with nucleons, using the N/D unitarization method. We find that, as the pion mass increases, the pole moves toward the real axis. For larger pion masses, at tree level, the pole falls to a specific point on u-channel cut and crosses to the adjacent Riemann sheet defined by the logarithmic u-channel cut. At the one-loop level, the pole does not meet the u-cut up to $m_{\pi} = 0.36$ GeV. We also re-examined the σ pole trajectory and found it to be in good agreement with the Roy equation analysis result.

I. INTRODUCTION

A subthreshold pole with quantum number $J^{PC} = 1/2^-$, named $N^*(920)$, has been established in the S_{11} channel of πN scatterings. It was first suggested in analysis of πN scattering data [1, 2] using the product representation for partial wave amplitudes (PWAs) [3–5], which originates from the correct treatment of the left hand cuts and unitarization [6, 7]. The pole is also confirmed using naive K-matrix approach [8] and N/D method [9]. Its existence is firmly established in a Roy-Steiner equation analysis in Ref. [10], with the pole location $\sqrt{s} = (918 \pm 3) - i(163 \pm 9)$ MeV, and is reconfirmed in Ref. [11] at $(913.9 \pm 1.6) - i(168.9 \pm 3.1)$ MeV. Its properties in turn naturally become a subject of research interest as much remains to be understood.

One might wonder why this state has a mass below the threshold but can still exhibit a large decay width to πN . This problem can be considered from two perspectives. The first perspective involves recognizing that the usual concept of particle decay—where one particle decays into two or more particles—is defined only within the framework of perturbation theory. Strictly speaking, unstable particles cannot appear as in- and out-states of the S matrix; they can only be defined as poles on the

second Riemann sheet of the analytically continued S matrix. These states exist solely as intermediate states in scattering processes. When a pole lies near the physical region, *i.e.* being a narrow resonance with a long lifetime, the imaginary part of the pole position approximately coincides with half of the decay width of the state calculated in perturbation theory. For poles far from the physical region, such as those associated with the σ and κ resonances, they can only be interpreted as intermediate states represented by poles of the S matrix. These states may induce moderate changes in phase shifts, which is why their existence has been a topic of extensive debate in the past. The second perspective is based on the usual understanding that the invariant mass of an unstable intermediate state does not have a fixed value but instead exhibit a mass distribution. A state with a large width has a very broad invariant mass spectrum, with its central value roughly corresponding to the pole mass. This means that there is a greater probability for such a state to have an invariant mass far from this central value compared to narrow resonances. In the case of $N^*(920)$, even though the central value of its mass distribution lies below the decay threshold, there remains some possibility for it to have an invariant mass above the threshold, allowing it to decay into πN .

The early work on the properties of $N^*(920)$ is its coupling to $N\gamma$ and $N\pi$ [12]. It is found that its coupling to $N\pi$ is considerably larger than that of $N^*(1535)$, while its coupling to $N\gamma$ is comparable to that of $N^*(1535)$. In this paper, we will focus on the $N^*(920)$ pole trajectory with varying pion masses.

In the literature, the σ pole trajectory with varying π masses has been a rather hot topic for discussions, see for example Refs. [13, 14] and references therein. Remarkably a model independent Roy equation analysis has been carried out to thoroughly resolve the issue [15]. The study of the σ pole trajectory with varying m_{π} is important, since it opens a new window in exploring non-perturbative strong interaction physics provided by lattice QCD calculations. An alternative study based on O(N) linear σ model [16, 17] finds similar results comparing with that of Ref. [15], hence providing further evidence that the σ meson may be more reasonably described as "elementary", in the sense that, like the pions, it is described by an explicit field degree of freedom in the effective chiral lagrangian¹⁾. Inspired by this, in this paper we adopt the effective lagrangian with a linearly realized chiral symmetry. Specifically, we use the renormalizable toy linear σ model with nucleon fields, though it is known that renormalizability condition is not a physical requirement when describing low-energy hadron physics. In short, we use the linear σ model rather than the γ PT lagrangian, mainly for theoretical considerations²⁾, though we believe the two give more or less the same results at a qualitative level.

In the following we begin with a brief introduction of the linear σ model with nucleons in Sec. II, and calculate the σ pole trajectory using the [1,1] Padé approximation in Sec. III. Since it has been verified that the unitarity approximation does provide a similar σ pole trajectory as comparing with Ref. [15], it is satisfactory to use the same approximation method to further explore the $N^*(920)$ trajectory, which will also be discussed in Sec. III. Sec. IV is devoted to discussions and conclusions.

II. A BRIEF REVIEW OF LINEAR σ MODEL

The linear σ model [21] (LSM) lagrangian with a nucleon field can be written as follows:

$$\mathcal{L} = \bar{\Psi}_0 i \gamma^{\mu} \partial_{\mu} \Psi_0 - g_0 \bar{\Psi}_0 \left(\sigma_0 + i \gamma_5 \vec{\tau} \cdot \boldsymbol{\pi}_0 \right) \Psi$$

$$+ \frac{1}{2} \left(\partial_{\mu} \sigma_0 \partial^{\mu} \sigma_0 + \partial_{\mu} \boldsymbol{\pi}_0 \cdot \partial^{\mu} \boldsymbol{\pi}_0 \right)$$

$$- \frac{\mu_0^2}{2} \left(\sigma_0^2 + \boldsymbol{\pi}_0^2 \right) - \frac{\lambda_0}{4!} \left(\sigma_0^2 + \boldsymbol{\pi}_0^2 \right)^2 + C \sigma_0 , \qquad (1)$$

where Ψ_0 is the isospin doublet denoting bare nucleon fields, and π_0 , σ_0 , μ_0 , g_0 , λ_0 are bare π meson triplet, σ field, a mass parameter, and couplings, respectively. The renormalized quantities are related to bare ones through:

$$\begin{cases} \psi_0 = \sqrt{Z_{\psi}} \psi, \\ (\sigma_0, \boldsymbol{\pi}_0) = \sqrt{Z_{\phi}} (\sigma, \boldsymbol{\pi}), \\ \mu_0^2 = \frac{1}{Z_{\phi}} (\mu^2 + \delta \mu^2), \\ g_0 = \frac{Z_g}{Z_{\psi} \sqrt{Z_{\phi}}} g, \\ \lambda_0 = \frac{Z_{\lambda}}{Z_{\phi}^2} \lambda. \end{cases}$$

$$(2)$$

Spontaneous chiral symmetry breaking (χSB) occurs when the σ vacuum expectation value (vev) $\langle \sigma \rangle = v \neq 0$, generating three zero-mass Goldstone bosons: π^i , i=1,2,3 in the absence of explicit χSB term $C\sigma_0$. To perform a perturbative calculation, one shifts $\sigma \to \sigma + v$ such that $\langle \sigma \rangle = 0$ and gets,

$$\mathcal{L} = \bar{\psi} \left[\partial /\!\!\!/ - m_N - g \left(\sigma + i \pi \cdot \tau \gamma_5 \right) \right] \psi$$

$$+ \bar{\psi} \left[-\delta m_N - \delta g \left(\sigma + i \pi \cdot \tau \gamma_5 \right) + i \left(Z_{\psi} - 1 \right) \partial \right] \psi$$

$$+ \frac{1}{2} \left[\left(\partial_{\mu} \sigma \right)^2 + \left(\partial_{\mu} \pi \right)^2 - m_{\sigma}^2 \sigma^2 - m_{\pi}^2 \pi^2 \right]$$

$$+ \left(Z_{\phi} - 1 \right) \left(\left(\partial_{\mu} \sigma \right)^2 + \left(\partial_{\mu} \pi \right)^2 \right) - \delta m_{\pi}^2 \pi^2 - \delta m_{\sigma}^2 \sigma^2 \right]$$

$$- \frac{\lambda}{4!} \left[\sigma^4 + \pi^4 + 4 v \sigma (\sigma^2 + \pi^2) + 2 \sigma^2 \pi^2 \right]$$

$$- \frac{\lambda}{4!} \left[Z_{\lambda} - 1 \right) \left[\sigma^4 + \pi^4 + 4 v \sigma (\sigma^2 + \pi^2) + 2 \sigma^2 \pi^2 \right]$$

$$- \sigma \left[v \left(m_{\pi}^2 + \delta m_{\pi}^2 \right) - C \sqrt{Z_{\phi}} \right], \tag{3}$$

with

$$m_N = gv$$
, $m_\sigma^2 = \mu^2 + \frac{1}{2}\lambda v^2$, $m_\pi^2 = \mu^2 + \frac{1}{6}\lambda v^2$. (4)

The renormalization constants are defined as

$$\begin{cases}
\delta m_N = m_N (Z_g - 1), \\
\delta g = g(Z_g - 1), \\
\delta m_\pi^2 = \delta \mu^2 + \frac{1}{6} (Z_\lambda - 1) \lambda v^2, \\
\delta m_\sigma^2 \equiv \delta \mu^2 + \frac{1}{2} (Z_\lambda - 1) \lambda v^2.
\end{cases}$$
(5)

¹⁾ Early studies using large N_c (number of colors) arguments also support such a suggestion [18–20].

²⁾ For example, at high temperatures, it is easy to restore the O(4) symmetry using linear σ model. On the contrary, in the χ PT framework, such a restoration is still absent [16, 17].

From Eq. (4), we obtain the relation between m_{π} and m_{σ} :

$$m_{\sigma}^2 = m_{\pi}^2 + \frac{1}{3}\lambda v^2 \,. \tag{6}$$

This relation holds if the renormalization constant Z_{λ} is chosen as

$$Z_{\lambda} = 1 - \frac{3(\delta m_{\pi}^2 - \delta m_{\sigma}^2)}{\lambda v^2} \,. \tag{7}$$

The other renormalization constants are determined by the following conditions, as done in Ref. [22]:

• To determine δm_{π}^2 and Z_{ϕ} , we demand that the full π propagator $\Delta_{\pi}(s)$ satisfies

$$i\Delta_{\pi}^{-1}(m_{\pi}^2) = 0, \qquad i\frac{d\Delta_{\pi}^{-1}(s)}{ds}\bigg|_{s=m_{\pi}^2} = 1.$$
 (8)

• To determine δm_{σ}^2 : we require that the real part of the inverse σ propagator, $i\Delta_{\sigma}^{-1}(s)$, vanish when $s \to m_{\sigma}^2$, *i.e.*,

$$\text{Re}[i\Delta_{\sigma}^{-1}(m_{\sigma}^{2})] = 0$$
. (9)

Notice that the parameter m_{σ} cannot be identified as the σ pole mass when $m_{\sigma} > 2m_{\pi}$ since $\mathrm{i}\Delta_{\sigma}^{-1}(m_{\sigma}^2)$ is complex in this situation. On the other hand, if m_{π} increases such that $m_{\sigma} < 2m_{\pi}$, then $\mathrm{i}\Delta_{\sigma}^{-1}(m_{\sigma}^2)$ becomes real and m_{σ} corresponds to the pole mass.

• To determine Z_{ψ} and Z_g : we require that the full nucleon propagator $\Delta_N(p)$ behaves as:

$$i\Delta_N^{-1}(m_N) = 0 ,$$

 $i\frac{d\Delta_N^{-1}(p)}{dp'}\Big|_{p'=m_N} = 1 .$ (10)

The results for the renormalization constants and counterterms under these renormalization conditions are listed in Appendix A.

In LSM, there are four free parameters: λ , m_{σ} , m_{π} , g. From Eqs. (6) and (4), the vacuum expectation value v and the nucleon mass m_N are expressed as:

$$v^{2} = \frac{3(m_{\sigma}^{2} - m_{\pi}^{2})}{\lambda}, \quad m_{N} = gv.$$
 (11)

In the physical situation, $m_{\pi} = 0.138 \text{ GeV}$, $m_{N} = 0.938 \text{ GeV}$, and v is identical to the pion decay constant f_{π} at tree level, whose experimental value is 0.093 GeV so that $g \simeq 10$. From PCAC, one also obtains $C \sqrt{Z_{\phi}} = f_{\pi}m_{\pi}^{2}$, and the pion decay constant f_{π} are related to v by [23]:

$$v = f_{\pi} m_{\pi}^2 i \Delta_{\pi}(0) . \tag{12}$$

At the one-loop level, this relation becomes:

$$\frac{\lambda^2 v^2}{144\pi^2} \left[\left(B_0(m_\pi^2, m_\pi^2, m_\sigma^2) - B_0(0, m_\pi^2, m_\sigma^2) \right) / m_\pi^2 - B_0'(m_\pi^2, m_\pi^2, m_\sigma^2) \right] - \frac{g^2 m_\pi^2}{4\pi^2} B_0'(m_\pi^2, m_N^2, m_N^2) = \frac{f_\pi}{v} - 1 .$$
(13)

Numerical tests reveal that the left-hand side of this equation has a negligible effect within the parameter regime used in our following calculations [22]. Therefore, f_{π} is still approximately equal to the vev v at the one-loop level¹⁾.

Since our purpose of using the LSM is to approximate QCD, which has only two free parameters, i.e., gauge coupling or Λ_{QCD} and the quark mass, whereas LSM has four $(g, m_N, m_\sigma, m_\pi)$, this leaves some freedom for manipulation of m_{π} dependence of parameters. In principle, only two parameters are independent for the LSM to serve as a low-energy effective field theory of QCD. Since we are considering the m_{π} dependence, we can choose m_{π} as one independent parameter and select another parameter to be independent of m_{π} , leaving the other two parameters dependent on m_{π} . Given that χPT encodes the correct m_{π} dependence from QCD, it can be used to supply the missing m_{π} dependence in the LSM. Since f_{π} appears in both theories, we make use of χ PT results to fix the dependence of f_{π} on m_{π}^{2} , which has been calculated up to NNLO in Refs. [24, 25]. Rewriting in terms of F and m_{π} , f_{π} is expressed as [24, 25]

$$f_{\pi} = F \left[1 + F_4 \frac{m_{\pi}^2}{16\pi^2 F^2} + F_6 \left(\frac{m_{\pi}^2}{16\pi^2 F^2} \right)^2 \right],$$

$$F_4 = 16\pi^2 l_4^r - \log \frac{m_{\pi}^2}{\mu^2},$$

$$F_6 = \left(16\pi^2 \right)^2 r_F^r - 16\pi^2 \left(l_2^r + \frac{1}{2} l_1^r + 32\pi^2 l_3^r l_4^r \right) - \frac{13}{192}$$

$$+ \left(16\pi^2 (7l_1^r + 4l_2^r - l_4^r) + \frac{29}{12} \right) \log \frac{m_{\pi}^2}{\mu^2} - \frac{3}{4} \log^2 \frac{m_{\pi}^2}{\mu^2}, \quad (14)$$

¹⁾ We also tested fixing $v = f_{\pi}$ at the physical value without m_{π} dependence and found that this did not modify the pole trajectories too much. Thus, the pole trajectories are in fact quite insensitive to the m_{π} dependence of v.

²⁾ This may be somewhat equivalent to adding some high order contributions in LSM lagrangian.

where these low-energy constants (LECs) are obtained in Ref. [26] by a full analysis on lattice data. In the following calculations, we impose this condition to constrain the m_{π} dependence of v by using Eq. (12). Another constraint from χ PT is the m_{π} dependence of m_N . We require the dependence of m_N on m_{π} to match the $O(p^5)$ result of baryon χ PT [27]. From the second equation in (11), the m_{π} dependence of g is also fixed. With one remaining free parameter, from the first equation in (11), we consider two alternative simple assumptions to proceed: to fix m_{σ} such that λ is dependent on m_{π} or vice versa. Since these two choices produce similar qualitative results, we choose the first one in discussing the π m scatterings and only provide the results in πN scatterings for both choices.

III. THE TRAJECTORIES OF THE σ POLE AND THE $N^*(920)$ POLE

This section is devoted to the study of the σ pole and the $N^*(920)$ pole dependence on varying pion masses. This analysis is meaningful in understanding the non-perturbative aspects of low-energy strong interaction physics, especially in the era when lattice QCD studies become more and more prosperous¹⁾. For the former, the σ pole trajectory is well understood [15, 29], while knowledge of the $N^*(920)$ trajectory is absent yet, from either lattice QCD or analytical studies.

We will study the two trajectories based on the renormalizable linear σ model with nucleons. The reason why we choose such a model is already discussed in the introduction. We in the following firstly re-analyze the σ pole trajectory using [1,1] Padé approximation². It will be found that the trajectory obtained is in rather good agreement with that of Roy equation analyses and O(N) model results qualitatively. This is because, unlike the unitarization using χ PT amplitude, the t- and u-channel σ exchange is taken into account here, which is the requirement of crossing symmetry.

A. The σ pole location in the I, J = 0, 0 channel $\pi\pi$ scattering amplitude

Basically, there can be two ways to extract the σ pole location: one is from the σ propagator, another is from the unitarized $\pi\pi$ scattering amplitude. They are not equivalent under the approximations being used. The propagator is obtained by using a Dyson resummation of self energy bubble chain, and is essentially a one-loop calculation, whereas the pole in the unitarized amplitude contains

more complete dynamical input³⁾. Therefore we adopt the scattering amplitude to extract the pole locations.

The $\pi\pi$ elastic scattering amplitude is written as:

$$T_{\alpha\beta\gamma\delta}(s,t,u) = A(s,t,u)\delta_{\alpha\beta}\delta_{\gamma\delta} + B(s,t,u)\delta_{\alpha\gamma}\delta_{\beta\delta} + C(s,t,u)\delta_{\alpha\delta}\delta_{\gamma\beta},$$
(15)

where α, β, γ and δ are isospin indexes and s, t and u are Mandelstam variables subject to the constraints $s+u+t=4m_\pi^2$. A(s,t,u), B(s,t,u) and C(s,t,u) are Lorentz invariant amplitudes. The total isospin I=0 amplitude $T^0(s,t,u)$ can be derived as:

$$T^{0}(s,t,u) = 3A(s,t,u) + B(s,t,u) + C(s,t,u).$$
 (16)

Partial wave amplitude (PWA) is defined as

$$T_J^I(s) = \frac{1}{32\pi(s - 4m_\pi^2)} \int_{4m_\pi^2 - s}^0 dt P_J \left(1 + \frac{2t}{s - 4} \right) T^I(s, t, u) ,$$
(17)

where P_J is the Legendre polynomial. The elastic unitarity reads:

$$\operatorname{Im} T_{I}^{I}(s) = \rho(s, m_{\pi}, m_{\pi}) |T_{I}^{I}(s)|^{2}, \quad s > 4m_{\pi}^{2}, \quad (18)$$

with

$$\rho(s, m_1, m_2) = \frac{\sqrt{(s - (m_1 + m_2)^2)(s - (m_1 - m_2)^2)}}{s} \ . \tag{19}$$

The PWA has been calculated up to one-loop level within LSM, neglecting nucleon contributions. At tree level, the Feynman diagrams contributing to $\pi\pi$ scattering amplitudes are presented in Fig. 1.

The corresponding invariant amplitude A(s,t,u) reads:

$$A(s,t,u) = -\frac{\lambda^2 v^2}{9(s - m_{\sigma}^2)} - \frac{\lambda}{3} .$$
 (20)

The invariant amplitudes B(s,t,u) and C(s,t,u) are related to A(s,t,u) via crossing symmetry:

$$A(s,t,u) = B(t,s,u) = C(u,t,s)$$
. (21)

¹⁾ For a recent review to the related subjects, one is referred to Ref. [28].

²⁾ It is not at all obvious that Padé approximation leads to a satisfied solution since it may be spoiled by spurious poles [30]. But in linear σ model it works rather good, since crossing symmetry is preserved at least partially.

³⁾ To be more specific, at one loop, the self energy on the second sheet contains the pseudo-threshold but not the dynamical left hand cut (the crossed channel σ exchanges), which is presented anyway in unitarized scattering amplitudes. So the two solutions cannot be the same.

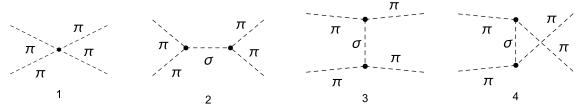

Fig. 1. The tree-level Feynman diagrams contributing to $\pi\pi$ scatterings.

From perturbative unitarity in LSM we have:

$$\operatorname{Im} T_{0l}^{0}(s) = \rho(s, m_{\pi}, m_{\pi}) |T_{0l}^{0}(s)|^{2}, \ 4m_{\pi}^{2} < s < 4m_{\sigma}^{2},$$
 (22)

where $T_{0l}^0(s)$ and $T_{0l}^0(s)$ denote the tree-level and the one-loop PWAs, respectively. Combining Eq. (16)–(17), the tree-level PWA is obtained as:

$$T_{0t}^{0}(s) = \frac{\lambda}{48\pi} \left(\frac{\left(3m_{\pi}^{2} + 2m_{\sigma}^{2} - 5s\right)}{2\left(s - m_{\sigma}^{2}\right)} + \frac{\left(m_{\sigma}^{2} - m_{\pi}^{2}\right)\log\left(\frac{s - 4m_{\pi}^{2} + m_{\sigma}^{2}}{m_{\sigma}^{2}}\right)}{\left(s - 4m_{\pi}^{2}\right)} \right). \tag{23}$$

At one-loop order, it is tedious to present all Feynman diagrams and their corresponding results, which exceed 50 diagrams [31]. Therefore, we will not include those amplitudes in this paper¹⁾. With Eq. (22), it is easy to prove that the [1,1] Padé approximant

$$T_0^{0[1,1]}(s) = \frac{T_{0t}^0(s)}{1 - T_{0t}^0(s)/T_{0t}^0(s)},$$
 (24)

satisfies elastic unitarity.

The σ resonance corresponds to the pole of the PWA on the second Riemann sheet (RSII) of complex s plane, or equivalently the zero of partial-wave S matrix:

$$S(s) = 1 + 2i\rho(s, m_{\pi}, m_{\pi})T_0^{0[1,1]}(s), \qquad (25)$$

on the first Riemann sheet (RSI).

According to Eq. (24), the numerator of $T_0^{0[1,1]}(s)$, *i.e.*, T_{0t}^0 , contains a first-order pole at m_σ^2 . When $m_\sigma > 2m_\pi$, in the denominator $1 - T_{0t}^0/T_{0t}^0$, there also exists a first-order pole because the loop-level amplitude $T_{0t}^0(s)$ contains a second-order pole at m_σ^2 from the one-loop σ propagator, as shown in the right diagram of Fig. 2. This causes

 $T_0^{0[1,1]}(s)$ to be finite at m_σ^2 . Thus, in this situation m_σ is not the pole mass of σ and the σ pole position would lie on the second Riemann sheet. On the contrary, with m_π growing up to $2m_\pi > m_\sigma$, the second-order pole in $T_{0l}^0(s)$ transforms to a first-order pole because the residue, being proportional to $\Sigma(m_\sigma^2)$, equals zero due to the renormalization condition (8). In this case, the denominator of Eq. (24) is finite at m_σ^2 , while the numerator remains a pole at m_σ^2 , which corresponds to the σ bound state.

To obtain the specific trajectories through numerical calculation, we choose a suitable $m_{\sigma} = 0.7$ GeV such that σ pole locates at about (0.47 – i0.16) GeV at physical pion mass.²⁾ Then, fixing this m_{σ} parameter and taking into account the relation between f_{π} and m_{π} , the trajectory of σ pole with increasing m_{π} is depicted in Fig. 2. The σ resonance falls down to real axis below the threshold from the complex plane above the threshold, becoming two virtual states (VSI and VSII) when m_{π} increases from the physical value to $m_{\pi} \simeq 0.32$ GeV. One of them (VSII) runs towards the threshold and finally crosses the threshold to the real axis below the threshold on RSI, turning into a bound state when $2m_{\pi} > m_{\sigma}$. On the other hand, the other virtual state (VSI) runs away from the threshold and collides with the third virtual state (VSIII), which appears from the left-hand cut when $m_{\pi} \simeq$ 0.22 GeV. Then these two virtual-state poles turn into a pair of resonance poles on the complex plane. The trajectory is similar to that of the Roy equation [15] and the N/D modified O(N) model [16], but now the critical point $(m_{\sigma}/2)$ when σ becomes a bound state can be determined analytically from the expression of Padé amplitude. Note that appearance of VSIII is a result of the σ exchange in the crossed channels, which is required by crossing symmetry. However, this effect is not taken into account in the unitarized \(\gamma PT \) calculations, and thus there is no such virtual state found there [13].

Having examined that the σ pole trajectory can be satisfactorily reproduced in the scheme of linear σ model with Padé unitarization, we are confident to proceed with studying the $N^*(920)$ pole trajectory in the linear σ model

¹⁾ The numerical code is available upon request.

²⁾ This width is slightly lower than that given by PDG. In order to get a larger width, one can tune $m_{\sigma} = 0.8 - 0.9$ GeV. But this choice is not satisfactory in another aspect: The σ only turns into a bound state when $m_{\pi} = 0.4 - 0.45$ GeV, which is somewhat larger than the result of Ref. [15], where the bound state appears when $m_{\pi} < 0.391$ GeV (see Fig. 2). Since in the present paper our purpose is only to obtain a qualitative picture of the pole trajectory, slightly different choices would not modify the main result of our paper.

with nucleon field, in the next subsection.

B. S_{11} channel of πN scattering amplitude

For the process $\pi^a(p) + N_i(q) \rightarrow \pi^{a'}(p') + N_f(q')$, the isospin amplitude can be decomposed as:

$$T = \chi_f^{\dagger} \left(\delta^{aa'} T^+ + \frac{1}{2} \left[\tau^{a'}, \tau^a \right] T^- \right) \chi_i, \qquad (26)$$

where τ^a (a = 1,2,3) are Pauli matrices, and χ_i (χ_f) corresponds to the isospin wave functions of the initial (final) nucleon states. The amplitudes with isospins I = 1/2, 3/2 can be written as:

$$T^{I=1/2} = T^+ + 2T^-$$
,
 $T^{I=3/2} = T^+ - T^-$. (27)

Taking into account the Lorentz structure, for isospin indices I = 1/2, 3/2, the amplitude can be represented as:

$$T^{I} = \bar{u}^{(s')}(q') \left[A^{I}(s,t) + \frac{1}{2} (p' + p') B^{I}(s,t) \right] u^{(s)}(q), \qquad (28)$$

with the superscripts (s), (s') denoting the spins of Dirac spinors and three Mandelstam variables $s = (p+q)^2$, $t = (p-p')^2$, $u = (p-q')^2$ obeying the constraint $s+t+u=2m_N^2+2m_\pi^2$. The channel with orbital angular momentum L, total angular momentum J, and total isospin I, denoted as $T(L_{2I2J})$ is defined as:

$$T_{\pm}^{I,J} = T(L_{2I2J}) = T_{++}^{I,J}(s) \pm T_{+-}^{I,J}(s), \quad L = J \mp \frac{1}{2},$$
 (29)

where the partial-wave helicity amplitudes are written as:

$$T_{++}^{I,J} = 2m_N A_C^{I,J}(s) + (s - m_\pi^2 - m_N^2) B_C^{I,J}(s),$$

$$T_{+-}^{I,J} = -\frac{1}{\sqrt{s}} \left[\left(s - m_{\pi}^2 + m_N^2 \right) A_S^{I,J}(s) + m_N \left(s + m_{\pi}^2 - m_N^2 \right) B_S^{I,J}(s) \right], \tag{30}$$

with

$$F_{C/S}^{I,J}(s) = \frac{1}{32\pi} \int_{-1}^{1} dz_s F^{I}(s,t) \left[P_{J+1/2}(z_s) \pm P_{J-1/2}(z_s) \right],$$

$$F = A, B$$
 (31)

 $z_s = \cos \theta$, with θ the scattering angle in the center of mass (CM) frame. The PWAs $T_{\pm}^{I,J}$ satisfy unitarity condition:

$$\operatorname{Im} T_{\pm}^{I,J}(s) = \rho(s, m_{\pi}, m_{N}) |T_{\pm}^{I,J}(s)|^{2}, \quad s > s_{R} = (m_{\pi} + m_{N})^{2}.$$
(32)

The full tree-level amplitudes of πN scattering in the LSM are given by three diagrams, as depicted in Fig. 3.

At tree level, the invariant amplitudes $A^{1/2}(s,t,u)$ and $B^{1/2}(s,t,u)$ are:

$$A^{1/2}(s,t,u) = -\frac{g\lambda v}{3(t-m_{\sigma}^2)},$$

$$B^{1/2}(s,t,u) = -g^2\left(\frac{3}{s-m_N^2} + \frac{1}{u-m_N^2}\right).$$
 (33)

According to Eq. (31), after partial-wave projection, the expressions of $A_{C/S}^{1/2,1/2}$ and $B_{C/S}^{1/2,1/2}$ are listed as follows,

$$A_C^{1/2,1/2}(s) = -\frac{g\lambda v}{96\pi k^2} \left(1 - \frac{(m_\sigma^2 + 4k^2)I(s)}{4k^2} \right) , \qquad (34)$$

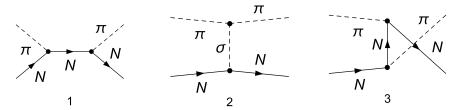

Fig. 3. The tree-level Feynman diagrams contributing to πN scatterings.

$$A_S^{1/2,1/2}(s) = -\frac{g\lambda v}{96\pi k^2} \left(1 - \frac{m_\sigma^2 I(s)}{4k^2} \right) , \tag{35}$$

$$B_C^{1/2,1/2}(s) = \frac{g^2}{32\pi} \left(-\frac{6}{s - m_N^2} + \frac{1}{k^2} \frac{m_N^2(s - c_L) \ln\left(\frac{s(s - c_R)}{m_N^2(s - c_L)}\right)}{4sk^4} \right),$$
(36)

$$B_S^{1/2,1/2}(s) = \frac{g^2}{32\pi} \left(\frac{6}{s - m_N^2} + \frac{1}{k^2} - \frac{(s - c_R) \ln\left(\frac{s(s - c_R)}{m_N^2(s - c_L)}\right)}{4k^4} \right),$$
(37)

with $k = \sqrt{s}\rho(s, m_{\pi}, m_N)/2$ being the magnitude of 3-momentum in CM and

$$I(s) = \ln\left(\frac{\left((m_{\pi}^2 - m_N^2)^2 - 2s(m_{\pi}^2 + m_N^2) + s(s + m_{\sigma}^2)\right)}{m_{\sigma}^2 s}\right). \tag{38}$$

 $B_C(s)$ and $B_S(s)$ contain the *u*-cut in the interval $(c_L = (m_N^2 - m_\pi^2)^2/m_N^2, c_R = m_N^2 + 2m_\pi^2)$ originating from the logarithmic term generated by *u*-channel nucleon exchange, as depicted in the 3rd diagram in Fig. 3. When $2m_\pi < m_\sigma < 2m_N$, the I(s) function contains circular arc cuts [8] centered at the origin with a radius of $m_N^2 - m_\pi^2$. At one-loop, the circular cut emerges due to continuous two-particle spectrum, which covers the circular arc cut.

After partial-wave projection, the perturbative PWAs are unitarized by N/D method¹⁾, which reduces to solving an integral equation for the N(s) function:

$$N(s) = N(s_0) + U(s) - U(s_0) + \frac{(s - s_0)}{\pi}$$

$$\times \int_{s_P}^{\infty} \frac{(U(s) - U(s'))\rho(s', m_{\pi}, m_N)N(s')}{(s' - s_0)(s' - s)} ds' . \quad (39)$$

Here, the subtraction point s_0 and subtraction value $N(s_0)$ can be chosen appropriately and U(s) function should be

analytic when $s > s_R$, such that N(s) only contains left-hand cuts

$$U(s) - U(s') = \frac{s - s'}{2\pi i} \int_{L} \frac{\operatorname{disc} M(\tilde{s})}{(\tilde{s} - s)(\tilde{s} - s')} d\tilde{s}, \qquad (40)$$

where the subscript L denotes integration along the left-hand cut. The discontinuity of the amplitude M(s) must be taken as input from the perturbative calculation. Since the dispersion relation of the amplitude on the left-hand cut essentially gives the amplitude with the right-hand cut integral subtracted (up to a polynomial), we can directly estimate U(s) - U(s') using the perturbative amplitude with its right-hand cut subtracted.

The amplitude satisfying the unitarity condition can be constructed as (we use M(s) to represent πN scattering amplitude in S_{11} channel):

$$M(s) = \frac{N(s)}{D(s)},$$

$$D(s) = 1 - \frac{s - s_0}{\pi} \int_{s_p}^{\infty} \frac{\rho(s')N(s')}{(s' - s)(s' - s_0)} ds'.$$
 (41)

One can solve this numerically using the inverse matrix method after introducing a cutoff Λ , such that the integral interval becomes (s_R, Λ) instead of (s_R, ∞) . In the following, s_0 and Λ , are fixed at the πN threshold s_R , and the nearest inelastic threshold $(m_N + m_\sigma)^2$ in perturbation theory, respectively. Since a once-subtracted dispersion relation is used, the integrand above this cut off is highly suppressed, and the final results are essentially independent of the cutoff choice.

At tree level, since the amplitude, denoted as M_t for tree level, already has no right-hand cut, we set U(s) equal to $M_t(s)$, and $N(s_0)$ equal to $M_t(s_0)$ which fixes $M(s_0) = M_t(s_0)$. Starting from m_σ at 0.55 GeV², we have performed two sets of calculations: one with fixed m_σ and the other with fixed λ as m_π increases. A pole at (0.94-0.14i) GeV corresponding to $N^*(920)$ resonance is found on the second Riemann sheet with physical pion and nucleon mass. The pole trajectories on RSII, with increasing pion mass in both cases are shown in Fig. 4 with

¹⁾ Here N/D method is used to avoid spurious poles which may present in the amplitude using Padé approximation.

²⁾ Here the m_{σ} is chosen slightly different from $\pi\pi$ case, since the $N^*(920)$ pole is close to the Roy-equation result with this choice.

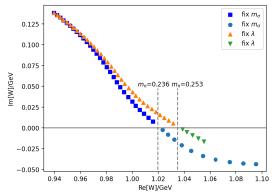

Fig. 4. (color online) The trajectories of $N^*(920)$ as m_{π} ranges from the physical value to 0.27 GeV for both cases of fixed m_{σ} and fixed λ at tree level. The points with Im[W] > 0 are the zeros (RSI) of S matrix for different pion masses and those with Im[W] < 0 are the zeros of the S_+ function (see the text). The vertical dashed lines correspond to roots obtained by solving equation (43) for $m_{\pi} = 0.236 \text{ GeV}$ and 0.253 GeV, respectively. We also tested the cases with cut offs at 2 GeV² and 3 GeV² respectively and found no distinguishable differences in the results.

 $\text{Im}W > 0 \ (W \equiv \sqrt{s}) \text{ points.}$

The imaginary part of N^* pole position decreases while the real part increases as m_{π} grows, causing the poles to approach the u-cut bounded by two branch points at c_R and c_L . Since the two conjugate N^* poles on RSII correspond to zeros of the S matrix on RSI, we analyze these zeros. After the zeros reach the u-cut, two possibilities arise: (1) the zeros separate on the real axis after collision, generating two virtual state zeros; (2) the zeros cross the u-cut and enter adjacent sheets defined by the logarithmic branch of the u-cut. However, we will show that the first senario is impossible for πN scattering.

In the first senario, if the N^* zeros reach the u-cut at $s_* \in (c_L, c_R)$ at critical pion mass \tilde{m}_{π} , and then separate to two virtual states, this implies that s_* must be a second-order zero of the S matrix. A necessary condition is that s_* is also a second-order zero of the imaginary part of S matrix, i.e., $\text{Im}[S(s_*)] = 0$ and $\text{Im}[S'(s_*)] = 0$. The first condition gives

$$2i\rho(s_*, m_\pi, m_N)\text{Im}[M(s_*)] = 0$$
, (42)

as $2i\rho(s_*, m_\pi, m_N)$ is real on the *u*-cut. Notice that the sole contribution to the imaginary part of PWA arises from the *u*-channel nucleon pole $\frac{g}{u-m_N^2}$ in the partial wave projection, which is non-perturbative and remains valid to all orders perturbative expansions.¹⁾ Thus, the zero of the imaginary part of PWA on the *u*-cut coincides with the

condition for tree level $\text{Im} M_t(s)$. According to the expression of $M_t(s)$, the condition $\text{Im} M_t(s) = 0$ on the *u*-cut reduces to

$$(m_N - m_\pi - W)(m_N + m_\pi - W)[m_N(m_N - W)(m_N + W)^2 - m_\pi^4] = 0,$$

$$W \equiv \sqrt{s}.$$
(43)

This equation has only one solution, located at $W_* \simeq m_N - \frac{m_\pi^4}{4m_N^3}$ inside *u*-cut.

Similarly, the condition $\text{Im}[S'(s_*)] = 0$ requires that the derivative of the left-hand side of Eq. (43) also vanish at the same point. However, this is impossible: differentiating the left-hand side of Eq. (43) yields $m_N(m_N - 3W)(m_N + W)$ (considering only the term inside the brackets), whose only reasonable root $W'_* = m_N/3$ does not satisfy Eq. (43). Therefore, the existence of a second-order zero is excluded. Thus the first scenario is ruled out.

In the context of the N/D method, the zero point of the S matrix at s_* requires

$$1 + 2\mathrm{i}\rho(s_*, m_\pi, m_N) M(s_*) = \frac{D(s_*) + 2\mathrm{i}\rho(s_*, m_\pi, m_N) N(s_*)}{D(s_*)} = 0 \ . \tag{44}$$

Since the function D(s) is real on the left-hand cuts, the requirement ImS = 0 leads to

$$2i\rho(s_*, m_\pi, m_N) \text{Im}[N(s_*)] = 2i\rho(s_*, m_\pi, m_N) \text{Im}[M_t(s_*)] = 0 ,$$
(45)

where we have used the fact that $2i\rho(s_*, m_\pi, m_N)$ is real on the left-hand cut. Thus, the necessary condition for the S matrix to vanish at s_* is $\text{Im} M_t(s_*) = 0$ which is reduced to (43). Notably, the property that the zero of the imaginary part of S matrix on the u-cut coincides with the zero of $\text{Im} M_t(s)$ is not only preserved in the N/D method but also respected by Padé or K-matrix unitarizations. A proof of this statement is provided in Appendix B.

It is, however, worth mentioning that the first scenario we have just excluded is actually what occurs in the case of $\pi\pi$ scatterings (see Fig. 5).

Having excluded Case 1, the only remaining possibility is that the N^* zeros cross the u-cut and enter adjacent Riemann sheets defined by the logarithmic branch of the u-cut. To trace the zeros further, the S matrix must be analytically continued onto these sheets. The analytically continued S matrix from the upper (lower) half-plane to the adjacent lower (upper) half-plane, denoted by S_+

¹⁾ The circular cut does not affect the imaginary part of PWA on the u-cut despite intersecting it.

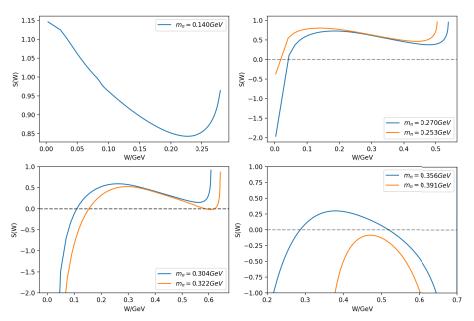

Fig. 5. (color online) The S matrix values for $\pi\pi$ scatterings between the left hand cut and the threshold using the results of the previous section. Initially, no S-matrix zeros exist in this region (upper-left subfigure). As m_{π} increases, a virtual-state zero (VSIII) emerges from the left-hand cut (upper-right). The sigma resonance turns into virtual-state zeros when the S matrix's local minimum contacts the real axis, generating a second-order zero precisely at this point. Subsequently, the two virtual-state zeros (VSI and VSII) split apart along the real axis (lower-left). VSI later becomes a bound-state pole of the S-matrix, leaving two virtual-state zeros (VSII and VSIII). These two zeros then coalesce on the real axis and move into the complex plane as resonance zeros (lower-right).

 (S_-) , can be obtained by adding $\pm 2\pi i$ to the logarithmic function $\ln(\frac{s(s-c_R)}{m_N^2(s-c_L)})$ in the unitarized S matrix on RSI.Therefore, after N^* crosses the u-cut, it can be followedcontinuously as a zero of S_+ on the adjacent lower half-plane, or equivalently, as a zero of S_- on the adjacent uppert half-plane. Fig. 4 shows how the zeros approach the u-cut, cross it at the critical point (marked by vertical dashed lines in Fig. 4) where Im[S] vanishes, and subsequently become the zeros of the analytically continued S_+ as m_π increases for both schemes: fixed m_σ and fixed λ .

Notably, tracing the poles across the u-cut starting from RSII is consistent with tracing the zeros starting from RSI. The S^{II} (S matrix on the RSII) is defined

$$S^{II}(s) = \frac{1}{S(s)}$$
 (46)

Modifying the logarithmic function $\ln\left(\frac{s(s-c_R)}{m_N^2(s-c_L)}\right)$ in $S^{II}(s)$ similarly results in

$$S_{\pm}^{II}(s) = \frac{1}{S_{+}(s)}$$
 (47)

Therefore, the zeros of S_{\pm} correspond to the poles of S_{\pm}^{II} .

In the above, we have actually established a mathematical theorem: if the zero reaches the u-cut, it must meet the cut at $W = W_*$ as defined by Eq. (43), and then cross onto the adjacent sheet. Nevertheless, this theorem does not explain why the pole should move toward the real axis. Thus, the next question is whether the zero will ever approach the u-cut and if so, why. At tree level, the N^* resonance does indeed reach the u-cut. However, there may still exist other possibilities for the N^* pole of the amplitude: it could move onto the real axis within the interval (c_R, s_R) outside the u-cut, or it may never touch the real axis at all. To further explore these possibilities, we extend the calculations to one-loop level.

At one-loop level, parameter $N(s_0)$ is set equal to $M_t(s_0) + M_t(s_0)$ and U(s) and the amplitude is written as:

$$U(s) = M_t(s) + M_l(s) - \frac{s}{\pi} \int_{s_P} \frac{\rho(s', m_\pi, m_N) M_t^2(s')}{s'(s' - s)} ds', \quad (48)$$

with $M_l(s)$ denoting the one-loop correction to the PWA. The full one-loop amplitude has been known [32], and after partial-wave projection, however, the PWA expression is too lengthy to present here¹⁾. The third term in the above expression ensures U(s) to be analytic in the interval $(s_R, (m_N + m_\sigma)^2)$ and remains consistent with perturbat-

¹⁾ The code is also available upon request.

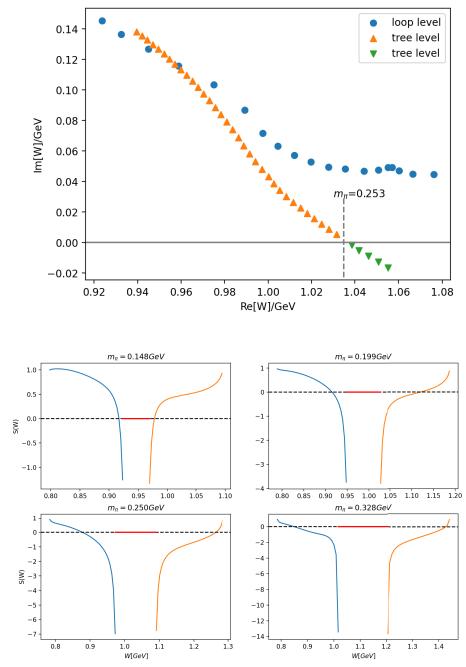

Fig. 6. (color online) Up: The dot points and triangle points denote the trajectories of $N^*(920)$ with m_{π} variation from 0.138 GeV to 0.360 GeV, at one-loop level and tree level for fixed λ , respectively. Down: the values of S matrix at one-loop level in intervals (s_L, c_L) and (c_R, s_R) on the first Riemann sheet. The red solid lines in the middle of the dashed lines denote the u-cuts.

ive unitarity:

$$\text{Im} M_l(s) = \rho(s, m_{\pi}, m_N) |M_l(s)|^2, \quad s > s_R.$$
 (49)

The nearest inelastic cut in the one-loop amplitude lies above $(m_{\sigma} + m_N)^2$ on the real axis, and thus we fix the cutoff $\Lambda = (m_N + m_{\sigma})^2$ such that the unitarized amplitude satisfies the single channel unitary condition in the interval $(s_R, (m_N + m_{\sigma})^2)$.

A pole at (0.92-0.15i) GeV corresponding to $N^*(920)$, can be found on the second sheet with physical pion and nucleon masses. The pole trajectories of $N^*(920)$ for both the tree level and the one-loop level as m_{π} increases, are shown in Fig. 6. At one-loop level, the trend of the $N^*(920)$ trajectories is similar to that at tree level: both initially move toward the real axis. However, as m_{π} becomes larger, the difference emerges. The one-loop zero does not appear likely to fall onto the real axis, at

least up to $m_{\pi} = 0.36$ GeV. We do not further test larger m_{π} since chiral expansions, which constrains the m_{π} dependence of m_N and f_{π} in our calculations, may become increasingly inaccurate at larger m_{π} .

We also studied the behavior of the two virtual states [33] lying in the intervals $(s_L = (m_N - m_\pi)^2, c_L)$ and (c_R, s_R) , respectively. The values of S matrix, calculated with one-loop level input in the two intervals on the first Riemann sheet, are plotted in Fig. 6. This demonstrates that the S matrix equals to unity at s_L and s_R by definition, while it tends to negative infinity as s is close to the two branch points c_L and c_R . As a result, a zero point occurs inside each interval. The calculation reveals that the virtual states move toward s_R or s_L with increasing m_π .

IV. DISCUSSIONS AND CONCLUSIONS

In this paper, we have studied the σ pole trajectory and the $N^*(920)$ pole trajectory with varying m_{π} , in a linear σ model with nucleons, using certain unitarization approximations. The m_{π} dependence of f_{π} and m_{N} from the χ PT are also taken into account, which renders the LSM more reasonable in approximating the low-energy QCD. The σ pole trajectory is found to be in agreement with

previous studies [15, 16]. The result on $N^*(920)$ pole trajectory is novel. At tree level, the $N^*(920)$ pole is found to move towards the *u*-cut on the real axis on the second Riemann sheet with increasing m_{π} , ultimately crossing the *u*-cut and entering the adjacent Riemann sheet defined by the *u*-cut. At one-loop level, however, the $N^*(920)$ still remains on the complex-plane at $m_{\pi} = 0.36$ GeV and even at higher values. The intricate analytical structure of πN PWAs, including the circular cut and u-cut, which stems from the the dynamical complexity of πN interactions, increase the difficulty for predicting on the final fate of N^* . The results presented in this paper may be useful for comparison with future lattice studies on πN scatterings. The next interesting topics for future research would be to investigate the $N^*(920)$ pole trajectory in the presence of temperature and chemical potential, and to study the old concept of parity doublet model which may return with new ingredients.

APPENDIX A: THE EXPRESSIONS OF COUNTER TERMS AND RENORMALIZATION CONSTANTS

The counter terms and renormalization constants take following forms up to one-loop level,

$$Z_{\phi} = 1 - \frac{g^2}{4\pi^2} \left(B_0 \left(m_{\pi}^2, m_N^2, m_N^2 \right) + m_{\pi}^2 B_0' \left(m_{\pi}^2, m_N^2, m_N^2 \right) \right) - \frac{\lambda^2 v^2}{144\pi^2} B_0' \left(m_{\pi}^2, m_{\pi}^2, m_{\sigma}^2 \right), \tag{A1}$$

$$Z_{F} = 1 - \frac{g^{2}}{32\pi^{2}m_{N}^{2}} \left(3m_{\pi}^{2}B_{0} \left(m_{N}^{2}, m_{\pi}^{2}, m_{N}^{2} \right) + m_{\sigma}^{2}B_{0} \left(m_{N}^{2}, m_{N}^{2}, m_{\sigma}^{2} \right) - 3A_{0} \left(m_{\pi}^{2} \right) + 4A_{0} \left(m_{N}^{2} \right) - A_{0} \left(m_{\sigma}^{2} \right) \right)$$

$$+ \frac{g^{2}}{16\pi^{2}} \left(3m_{\pi}^{2}B_{0}^{\prime} \left(m_{N}^{2}, m_{\pi}^{2}, m_{N}^{2} \right) + m_{\sigma}^{2}B_{0}^{\prime} \left(m_{N}^{2}, m_{N}^{2}, m_{\sigma}^{2} \right) - 4m_{N}^{2}B_{0}^{\prime} \left(m_{N}^{2}, m_{N}^{2}, m_{\sigma}^{2} \right) \right) , \tag{A2}$$

$$Z_{g} = 1 + \frac{g^{2}}{16\pi^{2}m_{N}^{2}} \left(-3m_{\pi}^{2}B_{0}\left(m_{N}^{2}, m_{\pi}^{2}, m_{N}^{2}\right) - m_{\sigma}^{2}B_{0}\left(m_{N}^{2}, m_{N}^{2}, m_{\sigma}^{2}\right) + 3A_{0}\left(m_{\pi}^{2}\right) - 4A_{0}\left(m_{N}^{2}\right) + A_{0}\left(m_{\sigma}^{2}\right) \right) + \frac{g^{2}}{16\pi^{2}} \left(2B_{0}\left(m_{N}^{2}, m_{N}^{2}, m_{\sigma}^{2}\right) + 3m_{\pi}^{2}B_{0}'\left(m_{N}^{2}, m_{\pi}^{2}, m_{N}^{2}\right) + m_{\sigma}^{2}B_{0}'\left(m_{N}^{2}, m_{N}^{2}, m_{\sigma}^{2}\right) - 4m_{N}^{2}B_{0}'\left(m_{N}^{2}, m_{N}^{2}, m_{\sigma}^{2}\right) \right) , \tag{A3}$$

$$\delta m_{\pi}^{2} = \frac{\lambda^{2} v^{2}}{144\pi^{2}} \left(B_{0} \left(m_{\pi}^{2}, m_{\pi}^{2}, m_{\sigma}^{2} \right) - m_{\pi}^{2} B_{0}' \left(m_{\pi}^{2}, m_{\pi}^{2}, m_{\sigma}^{2} \right) \right) + \frac{\lambda}{96\pi^{2}} \left(5A_{0} \left(m_{\pi}^{2} \right) + A_{0} \left(m_{\sigma}^{2} \right) \right)$$

$$- \frac{g^{2}}{4\pi^{2}} \left(m_{\pi}^{4} B_{0}' \left(m_{\pi}^{2}, m_{N}^{2}, m_{N}^{2} \right) + 2A_{0} (m_{N}^{2}) \right) , \tag{A4}$$

$$\delta m_{\sigma}^{2} = \frac{\lambda^{2} v^{2}}{\pi^{2}} \left(\frac{\operatorname{Re} B_{0} \left(m_{\sigma}^{2}, m_{\pi}^{2}, m_{\pi}^{2} \right)}{96} + \frac{B_{0} \left(m_{\sigma}^{2}, m_{\sigma}^{2}, m_{\sigma}^{2} \right)}{32} - \frac{m_{\sigma}^{2} B_{0}^{\prime} \left(m_{\pi}^{2}, m_{\pi}^{2}, m_{\sigma}^{2} \right)}{144} \right) + \frac{\lambda}{32\pi^{2}} \left(A_{0} \left(m_{\pi}^{2} \right) + A_{0} \left(m_{\sigma}^{2} \right) \right) - \frac{g^{2} m_{\sigma}^{2}}{4\pi^{2}} \left(B_{0} \left(m_{\pi}^{2}, m_{N}^{2}, m_{N}^{2} \right) - B_{0} \left(m_{\sigma}^{2}, m_{N}^{2}, m_{N}^{2} \right) + m_{\pi}^{2} B_{0}^{\prime} \left(m_{\pi}^{2}, m_{N}^{2}, m_{N}^{2} \right) \right) - \frac{g^{2}}{4\pi^{2}} \left(2A_{0} \left(m_{N}^{2} \right) + 4m_{N}^{2} B_{0} \left(m_{\sigma}^{2}, m_{N}^{2}, m_{N}^{2} \right) \right) . \tag{A5}$$

The definitions of 1-point function $A_0(m^2)$ and 2-point function $B_0(p^2, m_1^2, m_2^2)$ are expressed as

$$\begin{split} A_0(m^2) &\equiv -16\pi^2 \mathrm{i} \int \frac{\mathrm{d}^4 k}{(2\pi)^4} \frac{1}{k^2 - m^2} \;, \\ B_0(p^2, m_1^2, m_2^2) &\equiv -16\pi^2 \mathrm{i} \int \frac{\mathrm{d}^4 k}{(2\pi)^4} \frac{1}{(k^2 - m_1^2)[(p+k)^2 - m_2^2]} \;. \end{split} \tag{A6}$$

 B'_0 denotes the derivation with respect to the first argument.

APPENDIX B: THE ZERO OF IMAGINARY PART OF S MATRIX IN OTHER UNITARY MODELS

In [1,1] Padé approximant, the amplitude M(s)

$$M(s) = \frac{M_t^2(s)}{M_t(s) - M_t(s)}.$$
 (B1)

The fact that $Im[M_l(s)] = Im[M_l(s)]$ on the *u*-cut causes

the zero of Im M(s) to be the same as that of $\text{Im} M_t(s)$ on the cut. As to the K-matrix, the amplitude is given by $^{1)}$

$$M^{-1}(s) = M_t^{-1}(s) - \tilde{B}(s),$$

$$\tilde{B}(s) = b_0 + \frac{s - s_*}{\pi} \int_{s_B} \frac{\rho(s', m_\pi, m_N)}{(s' - s_*)(s' - s)} ds'.$$
(B2)

Then, the ImS(s) on the *u*-cut reads:

$$\operatorname{Im}S(s) = \operatorname{Im}\left[\frac{1 - \tilde{B}(s)M_{t}(s) + 2i\rho(s, m_{\pi}, m_{N})M_{t}(s)}{1 - \tilde{B}(s)M_{t}(s)}\right]$$

$$= \frac{2i\rho(s, m_{\pi}, m_{N})\operatorname{Im}M_{t}(s)}{1 - \tilde{B}(s)(M_{t}^{*}(s) + M_{t}(s)) + \tilde{B}^{2}(s)|M_{t}(s)|^{2}},$$

$$s \in (c_{L}, c_{R}). \tag{B3}$$

Again, we get the same conclusion.

¹⁾ Using $i\rho(s, m_{\pi}, m_N)$ instead of $\tilde{B}(s)$ leads to same result.
