Abstract: Electroweak (EW) amplitudes in the gauge-Goldstone five-component formalism have a distinctive property: gauge symmetry is imprinted in the amplitudes, manifested as the massive Ward identity (MWI) $k^M \mathcal{M}_M = 0$. In this study, we used the HELAS package to numerically study gauge symmetry in EW amplitudes. First, we directly tested gauge symmetry by examining the MWI of amplitudes. Second, we modified the couplings within a vertex and among vertices to check if and how the MWI changes. Third, we tested gauge symmetry by considering the couplings modified by operators from the standard model effective field theory (SMEFT). Similar to the standard model, there are relations between different couplings that are protected by gauge symmetry. We observed that, if we modify the couplings to deviate from the relations, the MWI is violated. In contrast, the MWI is restored when the relations between couplings reduce to those in the SMEFT.

I. INTRODUCTION

The gauge cancellation of electroweak (EW) scattering amplitudes in the standard model (SM) [1–3] has been both a theoretical problem hindering physical analysis and a practical problem in numerical calculations. In recent years, a new framework for computing EW amplitudes based on Goldstone equivalence has been proposed and implemented in the software package HELAS [4]. The main ingredients of this framework are as follows: 1) taking Goldstone equivalence [5–7], so that the polarization vector of a massive vector boson has no k^μ term and is instead composed of its Goldstone component and a remnant gauge term; 2) combining the gauge components and their Goldstone components of fields or polarization vectors into single five-component objects at the level of polarization vectors, propagators, and vertices; and 3) imposing a special light-cone gauge defined by the gauge direction $n^\mu = (1, -\mathbf{k}/|\mathbf{k}|)$, dubbed the Feynman diagram gauge [4] or Goldstone equivalence gauge [8]. It has been demonstrated in Ref. [4] with many examples that EW amplitudes in this new scheme do not have gauge cancellation, thereby solving a long-standing

problem. Further studies on this topic can be found in Refs. [9–15]. Earlier but incomplete treatment of the five-component formalism can be found in Refs. [16–18].

The new framework in Ref. [4] is essentially a reorganization and combination of "pieces" from existing Feynman rules. Although ideal to be combined with the Feynman diagram gauge, it can also be applied to other gauges, such as the Feynman gauge. Therefore, it is necessary to distinguish the five-component framework from any specific choice of gauge. Additionally, since the framework relies on the Goldstone equivalence theorem [5–7] in an essential way, it is appropriate to refer to it as the Goldstone equivalence (GE) representation of Feynman rules, as we will do from now on. Correspondingly, the standard Feynman rules will be called the gauge representation, as they exclusively treat the physical content of massive vector bosons as quanta of gauge fields.

Although the absence of gauge cancellation is crucial for practical applications, it is not the only important property of the GE representation of EW Feynman rules. Another intriguing property is that the GE representation directly imprints gauge symmetry at the level of amplitudes, as expressed by the massive Ward identity

(MWI), which is named in analog to its massless counterpart. Specifically, for a scattering amplitude $\mathcal{E}^{\mu(*)}(k)\mathcal{M}_\mu$ involving an external vector boson V with mass m_V and four-momentum k^μ , the MWI is [5–7, 19]

$$k^\mu \mathcal{M}_\mu = \mp i m_V \mathcal{M}(\varphi), \quad (1)$$

where the $- (+)$ sign corresponds to the case where the vector boson is in the initial (final) state, and $\mathcal{M}(\varphi)$ represents the amplitude obtained by replacing the vector boson with the corresponding Goldstone boson φ . The MWI (1) is a fundamental identity for a spontaneously broken gauge theory, *e.g.*, the EW gauge theory. This study aimed to investigate the gauge symmetry of EW amplitudes using the numerical tool HELAS [4, 20, 21].

Similar to the Ward identity in gauge theories with massless gauge bosons, the MWI guarantees precise relations among different diagrams of an amplitude, which further imply exact relations among different vertices or, equivalently, different couplings within the same theory. Considering the example of $W^+W^- \rightarrow W^+W^-$ with the helicity combination of TTTT, where T represents a transverse polarization, the amplitude includes three vertices WWZ , WWA , and $WWWW$ with couplings g_{WWZ} , g_{WWA} , and g_{WWWW} . The Ward identity requires that

$$g_{WWWW} = g_{WWZ}^2 + g_{WWA}^2. \quad (2)$$

Conversely, any deviation from this relation would result in violations of the gauge symmetry and the Ward identity. When the helicity combination involves longitudinal components, the precise relations the MWI brings about not only involve couplings of gauge bosons, but also those of Goldstone bosons and the Higgs boson. Thus, the structure of gauge symmetry is much richer in massive amplitudes, which we study in detail. Moreover, the gauge symmetry and MWI are not limited to the SM and can be applied to other theories. One theory of particular interest is the standard model effective field theory (SMEFT) [22–27], which is a direct extension of the SM.

The remainder of this paper is organized as follows. In Section II, we provide a brief introduction to the GE representation of EW interactions, emphasizing the relations among different couplings and parameters. In Section III, we directly test the EW gauge symmetry with the MWI (1) across multiple processes and helicity combinations. In Section IV, we examine the EW gauge symmetry through anomalous couplings, including both within individual vertices and among multiple vertices. Finally, in Section V, we study the connection between anomalous couplings (Higgs self-couplings and Yukawa couplings) and certain SMEFT operators using the MWI. We demonstrate that, when the anomalous couplings are

adjusted according to the SMEFT operators, the MWI is satisfied, ensuring the gauge invariance and self-consistency of the theory.

II. GE REPRESENTATION OF EW INTERACTIONS

In this section, we describe key ingredients of the GE representation, including polarization vectors, gauge choice, propagator, vertices, and Feynman rules.

A. Polarization Vectors in the Five-Component Formalism

The central identity of our program is the MWI (1), which essentially states the equivalence between the k^μ terms in gauge fields and the corresponding Goldstone fields. Moreover, the longitudinal polarization vector of a massive vector boson V with four-momentum k^μ can be decomposed into

$$\epsilon_L^\mu(k) = \frac{k^\mu}{m_V} - \frac{m_V}{n \cdot k} n^\mu \quad (3)$$

with $n^\mu = (1, -\mathbf{k}/|\mathbf{k}|)$, and the subscript L representing longitudinal polarization. We can eliminate the k^μ term in $\epsilon_L^\mu(k)$ by using the MWI, resulting in the amplitude with a longitudinal vector boson:

$$\mathcal{M}(\mathcal{V}_L) \equiv \epsilon_L^\mu(k) \mathcal{M}_\mu = -\frac{m_V}{n \cdot k} n^\mu \mathcal{M}_\mu - i \mathcal{M}(\varphi), \quad (4)$$

where the MWI (1) is used in the second step.

The generalization to multiple vector bosons is straightforward, but it leads to an excessive number of terms, making calculations cumbersome. To address this issue, we define five-component longitudinal polarization vectors in the GE representation by combining the gauge boson wave function and the Goldstone boson "wave function" as

$$\begin{aligned} \epsilon_L^M(k) &\equiv \left(-\frac{m_V n^\mu}{n \cdot k}, i \right) \quad \text{for initial state,} \\ \epsilon_L^{*M}(k) &\equiv \left(-\frac{m_V n^\mu}{n \cdot k}, -i \right) \quad \text{for final state,} \end{aligned} \quad (5)$$

with $\mu = 0, 1, 2, 3$ and $M = 0, 1, 2, 3, 4$. In addition, the five-component transverse polarization vectors are defined as $\epsilon_\pm^M(k) = (\epsilon_\pm^\mu(k), 0)$. Then, the MWI (1) can be rewritten as

$$k^M \mathcal{M}_M = 0 \quad \text{for incoming,} \quad k^{*M} \mathcal{M}_M = 0 \quad \text{for outgoing,} \quad (6)$$

with $\mathcal{M}^M \equiv (\mathcal{M}^\mu, \mathcal{M}(\varphi))$, and the five-component "mo-

momentum" $k^M \equiv (k^\mu, -im_V)$. The five-dimensional "metric" for index contraction is $g_{MN} \equiv \text{diag}(+1, -1, -1, -1, -1)$. The spin sum of the polarization vectors becomes

$$\sum_{s=\pm, L} \epsilon_s^M(k) \epsilon_s^{*N}(k) = -g^{MN} + \frac{k^M n^N + n^M k^{*N}}{n \cdot k}, \quad (7)$$

with $g^{MN} = \text{diag}(+1, -1, -1, -1, -1)$ and $n^M \equiv (n^\mu, 0)$. Writing the gauge and Goldstone components separately, Eq. (7) becomes

$$\sum_{s=\pm, L} \epsilon_s^M(k) \epsilon_s^{*N}(k) = \begin{pmatrix} -g^{\mu\nu} + \frac{k^\mu n^\nu + n^\mu k^\nu}{n \cdot k} & i \frac{m_V n^\nu}{n \cdot k} \\ -i \frac{m_V n^\mu}{n \cdot k} & 1 \end{pmatrix}. \quad (8)$$

The mixing between gauge and Goldstone degrees of freedom is manifest here. When $m_V \rightarrow 0$, they decouple from each other.

Because of the MWI (6), we can go further to state that the longitudinal polarization vector can be equivalently defined by an arbitrary shift:

$$\epsilon_L^M(k, \lambda) \equiv \left(-\frac{m_V n^\mu}{n \cdot k}, i \right) + \lambda \frac{k^M}{m_V} \quad (9)$$

which gives the same amplitudes for any value of λ . Choosing $\lambda = 1$ yields $\epsilon_L^M(k, 1) = (\epsilon_L^\mu(k), 0)$, which corresponds to the conventional case using Eq. (3). We refer to the case of $\lambda = 1$ as the gauge form of the longitudinal polarization. The case of $\lambda = 0$ corresponds to Eq. (5), which we call the GE form.

B. Gauge Choice and Propagator

The five-component formalism can also be naturally derived from the Lagrangian, which includes a term $m_V V_\mu \partial^\mu \varphi$ that mixes the gauge field with the Goldstone field after gauge symmetry breaking [4]. Therefore, it is natural to combine gauge and Goldstone components into one five-component object.

The GE representation, implemented through the five-component formalism, is compatible with any gauge except the unitary gauge, which eliminates Goldstone bosons from the Feynman rules. In the R_ξ gauges, the gauge-fixing Lagrangian term $-(\partial^\mu V_\mu - m_V \varphi)^2 / (2\xi)$ is introduced to cancel the gauge-Goldstone mixing term. This results in the propagator for a massive vector boson in the five-component formalism taking the form of

$$D^{MN}(k) = \frac{-ig^{MN}}{k^2 - m_V^2 + i\varepsilon} + \frac{i(1-\xi)}{(k^2 - m_V^2)(k^2 - \xi m_V^2)} \begin{pmatrix} k^\mu k^\nu & 0 \\ 0 & m_V^2 \end{pmatrix}. \quad (10)$$

Setting $\xi = 1$ yields the Feynman gauge.

To completely eliminate the k^μ terms, we can choose the gauge condition $n^\mu(x) V_\mu(x) = 0$, where $n^\mu(x)$ is the Fourier transformation of $n^\mu(k) = (1, -\mathbf{k}/|\mathbf{k}|)$, by adding the Lagrangian term $-[n^\mu(x) V_\mu(x)]^2 / (2\alpha)$. Its specific form is irrelevant here. Applying this to a massive gauge theory, the five-dimensional vector boson propagator becomes

$$D^{MN}(k) = \frac{-i}{k^2 - m_V^2} \left(g^{MN} - \frac{k^M n^N + n^M k^{*N}}{n \cdot k} \right) + \alpha \frac{k^M k^{*N}}{(n \cdot k)^2}. \quad (11)$$

The numerator of the gauge independent part is precisely the spin sum of polarization vectors in Eq. (7) for an on-shell momentum. Taking $\alpha \rightarrow 0$, we obtain the polarization vector in Eq. (9) with $\lambda = 0$. This is known as the Goldstone equivalence gauge or the Feynman diagram gauge [4].

C. Vertices and Feynman Rules

With the polarization vectors and propagator expressed in the five-component formalism, this framework can be naturally extended to vertices involving massive vector bosons. Accordingly, we introduce a double-line notation by overlapping a wavy line with a dashed line to represent the massive vector boson in Feynman rules: the wavy line represents the gauge components, whereas the dashed line represents the Goldstone component. As examples of this double-line notation, we illustrate the decomposition of the vector boson propagator in Fig. 1 and that of the WW_h vertex in Fig. 2.

The new form of vertices brings additional subtleties. For example, we denote the WW_h vertex as $V_{WW_h}^{MN}$, where the subscript indicates the vertex and the superscript represents indices. In the GE representation, a vertex involving massive vector bosons has multiple parameters. For instance, $V_{WW_h}^{MN}$ not only includes the pure gauge components $V_{WW_h}^{\mu\nu}$ with coupling g_{WW_h} but also involves the gauge-Goldstone components $V_{WW_h}^{\mu 4} = V_{W\varphi h}^\mu$ with coupling $g_{W\varphi h} = g_{\varphi W_h}$ and the pure Goldstone component $V_{WW_h}^{44} = V_{\varphi\varphi h}$ with coupling $\lambda_{\varphi\varphi h}$. We can further express the vertex as $V_{WW_h}^{MN}(g_{WW_h}, g_{\varphi W_h}, \lambda_{\varphi\varphi h}; m_h, m_W)$. However, these couplings are not independent in the SM. They are all determined by the gauge coupling g , excluding the mass

Fig. 1. Five-component vector boson propagator in the double-line notation.

Fig. 2. Five-component vertex of WWh in the double-line notation. The minus sign before φWh comes from the $g_{44} = -1$ component of the "metric" g_{MN} .

parameters. These relations originate from the spontaneous symmetry breaking of the EW theory, reflecting the underlying gauge symmetry. Similar relations also exist for other vertices, such as $ff'W$ and WWZ . Further details are discussed in Sec. IV.

Finally, let us examine the free parameters in the SM. The EW gauge and Higgs sectors of the SM contain only four free parameters, which we choose to be m_W , g , θ_W , and m_h , representing the W boson mass, $SU(2)_L$ gauge coupling, weak mixing angle, and Higgs boson mass, respectively. All the other parameters in these sectors are derived from them. For example, the Z boson mass is given by $m_Z = m_W / \cos \theta_W$, and the Higgs self-coupling is $\lambda_h = 2m_h/v^2 = g^2 m_h / (2m_W^2)$. In the fermion sector, each Yukawa coupling is defined as $\lambda_f = gm_f / (\sqrt{2}m_W)$, introducing an additional parameter, the corresponding fermion mass m_f . If we assume that the particle masses have been precisely measured and are treated as inputs, the free parameters in the EW sectors of the SM reduce to just two: g and θ_W .

III. DIRECT TEST OF GAUGE SYMMETRY

In this section, we directly test the gauge symmetry in EW scattering amplitudes using the MWI (6). We consider the EW processes $W^+W^- \rightarrow t\bar{t}$ and $W^+W^- \rightarrow W^+W^-$ as two examples, replacing the polarization vectors of W bosons in the amplitudes with the five-component momenta $k^{(*)M}$ and computing $k^M \mathcal{M}_M$ utilizing HELAS in the GE representation.

In Fig. 3, we show $k^M \mathcal{M}_M$ for $W^+W^- \rightarrow t\bar{t}$ as a function of $\cos \theta$, where θ is the scattering angle in the center-of-mass (CM) system. The CM energy and azimuthal angle are fixed as $\sqrt{s} = 1$ TeV and $\phi = 0$, respectively. In Figs. 3(a) and 3(b), the polarization vector of W^+ is replaced by k^M , with the helicities of $t\bar{t}$ fixed as $+-$ and the helicity of W^- set to be 0 (longitudinal polarization) and $+$. In Figs. 3(c) and 3(d), the setup is similar, except the helicities of $t\bar{t}$ are fixed as $++$. The blue solid lines represent the results including all tree-level diagrams,

demonstrating the MWI $k^M \mathcal{M}_M = 0$. The red dotted and green dashed lines correspond to the results excluding the t -channel diagram and those solely involving the t -channel diagram, respectively. These contributions are precisely opposite to each other, indicating a large and exact cancellation between different diagrams, as expected.

In Fig. 4, we present the results for $W^+W^- \rightarrow W^+W^-$, where one, two, and four polarization vectors of W bosons are replaced by one, two, and four five-component momenta, respectively. The helicities of the remaining W bosons are uniformly set to $+$. The blue lines represent the sums of all tree-level diagrams, whereas the red dotted, green dashed, and black dot-dashed lines correspond to the results for the contact, s -channel, and t -channel diagrams, respectively. Once again, we observe that the MWI is satisfied when all tree-level diagrams are included, confirming the gauge symmetry.

IV. TESTING GAUGE SYMMETRY THROUGH ANOMALOUS COUPLINGS

In the previous section, we confirmed that the gauge symmetry represented by the MWI ensures precise cancellation among various diagrams when one or multiple polarization vectors $\epsilon^M(k)$ are replaced by five-component momenta k^M . In this section, we take a different approach by modifying certain couplings to examine how the MWI is affected. Such a test of gauge symmetry through anomalous couplings can provide deeper insights into how different couplings and parameters are interrelated through gauge symmetry.

In the GE representation, any vertex involving massive vector bosons contains multiple couplings. This allows us not only to modify the couplings of individual vertices as a whole but also to adjust specific parameters within those couplings. The latter will be studied in Subsection IV.A with three-point vertices, whereas the former will be discussed in Subsection IV.B with four-point vertices.

Fig. 3. (color online) Testing the MWI by computing $k^M \mathcal{M}_M$ for $W^+ W^- \rightarrow t \bar{t}$.

Fig. 4. (color online) Testing the MWI by computing $k_M \mathcal{M}^M$ (a), $k_{1M} k_{2N} \mathcal{M}^{MN}$ (b), and $k_{1M} k_{2N} k_{3O}^* k_{4P}^* \mathcal{M}^{MNOP}$ for $W^+ W^- \rightarrow W^+ W^-$.

A. Three-point Vertices

In this subsection, we examine gauge symmetry through the analysis of three-point vertices, specifically focusing on the VVh , $ff'V$, and VVV vertices within the GE representation.

VVh vertex

The first type of vertices we study is the VVh vertices, which include the WWh and ZZh vertices. As discussed in Sec. II, a VVh vertex in the GE representation involves four sub-vertices: VVh , $V\phi h$, $V\phi h$, and $\phi\phi h$, with corresponding couplings g_{hVV} , $g_{V\phi h}$, $g_{\phi Vh}$, and $\lambda_{\phi\phi h}$. For the WWh vertex in the SM, the couplings are related to each other by the following relations:

$$WWh: \quad g = 2g_{W\phi h} = 2g_{\phi W h} = \frac{g_{WWh}}{m_W}, \quad \lambda_{\phi\phi h} = \frac{gm_h^2}{2m_W}. \quad (12)$$

We intend to test the MWI by modifying these couplings by

$$\begin{aligned} g_{WWh} &= gm_W(1 + \delta_{WWh}^1), & g_{W\phi h} &= \frac{g}{2}(1 + \delta_{WWh}^2), \\ g_{\phi W h} &= \frac{g}{2}(1 + \delta_{WWh}^3), & \lambda_{\phi\phi h} &= \frac{gm_h^2}{2m_W}(1 + \delta_{WWh}^4). \end{aligned} \quad (13)$$

The SM corresponds to $\delta_{WWh}^1 = \delta_{WWh}^2 = \delta_{WWh}^3 = \delta_{WWh}^4 = 0$.

$\delta_{WWh}^4 = 0$. For the ZZh vertex, we only need to replace m_W with m_Z in Eqs. (12) and (13). To facilitate a clearer comparison with the gauge representation, we leave g_{WWh} unchanged, ensuring $\delta_{WWh}^1 = 0$ at all times. Additionally, we enforce $\delta_{WWh}^2 = \delta_{WWh}^3 \equiv \delta_{WWh}^{23}$ when modifying the couplings, as the two sub-vertices $V\phi h$ and ϕVh belong to the same type.

The processes we choose to test gauge symmetry with the WWh vertex are $W^+W^- \rightarrow t\bar{t}$ and $W^+W^- \rightarrow hh$. We first compare the cross sections with respect to $\delta_{WWh}^{23,4}$ in both the unitary gauge and GE representation, and the results are shown in Fig. 5. As expected, when δ_{WWh}^{23} and δ_{WWh}^4 are nonzero, the cross sections in the GE representation deviate from those in the unitary gauge, which remain unchanged and retain the SM values. The larger the values of δ_{WWh}^{23} and δ_{WWh}^4 , the larger the deviations. Compared with $WW \rightarrow hh$, $WW \rightarrow t\bar{t}$ exhibits significantly lower sensitivity to δ_{WWh}^{23} and δ_{WWh}^4 . We must plot δ_{WWh}^{23} and δ_{WWh}^4 over the range $[-100, 100]$ for $WW \rightarrow t\bar{t}$ but only $[-1, 1]$ for $WW \rightarrow hh$. This is not surprising, given that the WWh vertex contributes to three channels of $WW \rightarrow hh$ but only one in $WW \rightarrow t\bar{t}$. Another notable observation is that the sensitivity of the cross section is much higher to δ_{WWh}^{23} than to δ_{WWh}^4 for $WW \rightarrow hh$, but the sensitivities are approximately the same for $WW \rightarrow t\bar{t}$.

Next, we compute $k_M \mathcal{M}^M$ or $k_{1M} k_{2N} \mathcal{M}^{MN}$ for these

Fig. 5. (color online) Cross sections of $WW \rightarrow hh$ (upper panels) and $WW \rightarrow t\bar{t}$ (lower panels) at $\sqrt{s} = 10$ TeV with varying δ_{WWh}^{23} and δ_{WWh}^4 in the unitary gauge (blue solid lines) and GE representation (red dotted lines).

processes as a way of testing gauge symmetry by replacing the polarization vectors of one or two W bosons with five-component momenta. The results are shown in Fig. 6 for $WW \rightarrow hh$ and Fig. 7 for $WW \rightarrow t\bar{t}$. For $WW \rightarrow t\bar{t}$, we analyze various helicity combinations. In certain helicity configurations, the results consistently vanish due to the violation of angular momentum conservation. Apart from these cases, the anomalous couplings lead to violations of the MWI. For $WW \rightarrow t\bar{t}$, the deviations for $\delta_{WW h}^{23}$ are larger than those for $\delta_{WW h}^4$.

$ff'V$ vertex

The $ff'V$ vertex has two sub-vertices: $ff'V$ and $ff'\varphi$. The $ff'V$ coupling can be parameterized as $-i\gamma^\mu(g_L P_L + g_R P_R)$, whereas the $ff'\varphi$ coupling is $y_L P_L + y_R P_R$. Similar to the VVh case, gauge couplings and Yukawa couplings are not independent, as the latter can be expressed in terms of the former.

For a charged current vertex, such as $u\bar{d}W$, we have

$$g_R = 0, \quad g_L = \frac{g}{\sqrt{2}}, \quad y_L = \frac{gm_d}{\sqrt{2}m_W}, \quad y_R = -\frac{gm_u}{\sqrt{2}m_W}. \quad (14)$$

For a neutral current vertex, such as $u\bar{u}Z$, we have

$$g_R = -\frac{Q_f g s_W^2}{c_W}, \quad g_L = g_R + \frac{g}{2c_W}, \quad y_L = -y_R = \frac{gm_u}{2m_W}, \quad (15)$$

with $s_W \equiv \sin\theta_W$ and $c_W \equiv \cos\theta_W$. To sum up, the $ff'\varphi$ couplings are Yukawa couplings y_f , which are related to the fermion masses m_f by $y_f = gm_f/(\sqrt{2}m_W)$. This relation is protected by gauge symmetry, and therefore, the breaking of gauge symmetry will be reflected in the violation of this relation.

Similar to VVh , we test gauge symmetry by modifying the $ff'V$ couplings as follows:

$$y_f = \frac{gm_f}{\sqrt{2}m_W}(1 + \delta_f). \quad (16)$$

The process we choose to examine gauge symmetry for the $ff'V$ vertex is $WW \rightarrow t\bar{t}$. This process is ideal because its t -channel diagram includes the $t\bar{b}W$ vertex, whereas its s -channel diagram includes the $t\bar{t}Z$ vertex, allowing us to examine both charged and neutral currents.

In Fig. 8, we demonstrate how the $WW \rightarrow t\bar{t}$ cross sections are changed when the couplings $y_{tZ}^{L/R}$ and $y_{tbW}^{b/t}$ are modified in both the unitary gauge and GE representation. Similarly, we show how $k_M \mathcal{M}^M$ or $k_{1M} k_{2N} \mathcal{M}^{MN}$ changes with the anomalous tbW couplings in Fig. 9, and

Fig. 6. (color online) $k_M \mathcal{M}^M$ and $k_{1M} k_{2N} \mathcal{M}^{MN}$ as functions of $\delta_{WW h}^{23}$ and $\delta_{WW h}^4$ for $WW \rightarrow hh$ with one or two W polarization vectors replaced by five-component momenta.

Fig. 7. (color online) $k_M \mathcal{M}^M$ and $k_{1M} k_{2N} \mathcal{M}^{MN}$ as functions of δ_{WWH}^{23} and δ_{WWH}^4 for $WW \rightarrow t\bar{t}$ with one or two W polarization vectors replaced by five-component momenta. The results for various helicity combinations are shown.

Fig. 8. (color online) Cross sections of $WW \rightarrow t\bar{t}$ in the unitary gauge and GE representation as functions of the anomalous couplings of tZ (upper panels) and tbW (lower panels).

Fig. 9. (color online) Testing the MWI by computing $k_M \mathcal{M}^M$ (upper panels) and $k_{1M} k_{2N} \mathcal{M}^{MN}$ (lower panels) with anomalous tbW couplings for the process $WW \rightarrow t\bar{t}$. Various helicity combinations are shown.

with the anomalous ttZ coupling in Fig. 10. As the figures show, gauge symmetry is broken when one of the components of tbW/ttZ couplings is modified, both in terms of cross sections and the MWI. For ttZ , the sensitivity of $k_M \mathcal{M}^M$ and $k_{1M} k_{2N} \mathcal{M}^{MN}$ to δ_{ttZ}^L is much higher than that to δ_{ttZ}^R . This is expected, as the SM ttZ vertex is dominated by the left-handed interaction. For tbW , the sensitivity to δ_{tbW}^t is much higher than that to δ_{tbW}^b . The reason is also not difficult to understand: the top Yukawa coupling is much larger than the bottom Yukawa coupling.

VVV vertex

In the SM, there are two VVV vertices, W^+W^+Z and W^+W^-A , either of which has three types of sub-vertices: VVV, $V\varphi V$, and $\varphi\varphi V$. There is no $\varphi\varphi\varphi$ -type vertex.

For the WWZ vertex, the couplings are related to each other by

$$\begin{aligned} g_{WWZ} &\equiv g_{C_W}, & g_{\varphi\varphi Z} &= \frac{g c_{2W}}{2 c_W}, & g_{\varphi W\varphi} &= \frac{g}{2}, & g_{W\varphi\varphi} &= \frac{g}{2}, \\ g_{WW\varphi} &= 0, & g_{W\varphi Z} &= \frac{e s_W m_W}{c_W}, & g_{\varphi WZ} &= -\frac{e s_W m_W}{c_W}, \end{aligned} \quad (17)$$

with $c_{2W} \equiv \cos 2\theta_W$ and $e = g s_W$. Following the analysis for the VVh and $f f' V$ vertices, we modify the couplings to test gauge symmetry as follows:

$$\begin{aligned} g_{\varphi\varphi Z} &= \frac{g c_{2W}}{2 c_W} (1 + \delta_{WWZ}^{234}), & g_{\varphi W\varphi} &= g_{W\varphi\varphi} = \frac{g}{2} (1 + \delta_{WWZ}^{234}), \\ g_{W\varphi Z} &= \frac{e s_W m_W}{c_W} (1 + \delta_{WWZ}^{567}) = -g_{\varphi WZ}. \end{aligned} \quad (18)$$

We examine the gauge symmetry of the WWZ vertex with both the $W^+W^+ \rightarrow W^+W^-$ and $WW \rightarrow t\bar{t}$ processes. In Figs. 11 and 12, we test the MWI by modifying δ_{WWZ}^{234} and δ_{WWZ}^{567} for $W^+W^+ \rightarrow W^+W^-$ and $WW \rightarrow t\bar{t}$, respectively. In both cases, the sensitivity of the violation of the MWI to δ_{WWZ}^{567} is higher than that to δ_{WWZ}^{234} , sometimes significantly so. This is somewhat surprising, as the $VV\varphi$ -type vertex that δ_{WWZ}^{567} modifies is suppressed by $e = g s_W$. However, they are typically proportional to m_W , providing an enhancement that effectively counterbalances the suppressive influence of the weak mixing angle θ_W .

B. Four-point Vertices

Gauge symmetry is reflected not only in the couplings within a single vertex but also in the relations among different vertices. For example, in the $WW \rightarrow WW$ process, where vertices, such as $WWWW$, WWZ , $WW\gamma$, and $WW h$, are involved, the MWI requires precise relations among their couplings. Any deviation from the SM values breaks gauge symmetry, similar to how it violates unitarity in the gauge representation. We modify the

Fig. 10. (color online) Testing the MWI by computing $k_M \mathcal{M}^M$ (upper panels) and $k_{1M} k_{2N} \mathcal{M}^{MN}$ (lower panels) with anomalous $t\bar{t}Z$ couplings for the process $WW \rightarrow t\bar{t}$. Various helicity combinations are shown.

Fig. 11. (color online) Testing the MWI by computing $k_{1M} k_{2N} \mathcal{M}^{MN}$ (upper panels), and $k_{1M} k_{2N} k_{3O}^* k_{4P}^* \mathcal{M}^{MNOP}$ (lower panels) with anomalous WWZ couplings for the process $W^+ W^- \rightarrow W^+ W^-$. In the upper panels, various helicity combinations are shown.

Fig. 12. (color online) Testing the MWI by computing $k_M \mathcal{M}^M$ (upper panels) and $k_{1M} k_{2N} \mathcal{M}^{MN}$ (lower panels) with anomalous WWZ couplings for the process $WW \rightarrow t\bar{t}$. Various helicity combinations are shown.

overall couplings of the vertices to test the MWI. The processes we choose are $W^+W^- \rightarrow W^+W^-$, $W^+W^- \rightarrow hh$, and $W^+W^- \rightarrow t\bar{t}$.

For $W^+W^- \rightarrow W^+W^-$, we separately vary the overall couplings of the WWh , WWZ , and WWW vertices and compute $k_M \mathcal{M}^M$. In Fig. 13, we show the results, listing different helicity combinations in the process. As expected, we can observe the violation of the MWI when the anomalous couplings are nonzero. This violation is most sensitive to δ_{WWZ} and δ_{WWW} .

One interesting observation is that, in most helicity combinations, $k_M \mathcal{M}^M$ remains zero or close to zero. This reminds us to be careful in selecting helicities when testing the gauge symmetry of massive amplitudes. The exact vanishing of $k_M \mathcal{M}^M$ in the presence of an anomalous δ_{WWZ} appears to be due to angular momentum conservation: the amplitude vanishes when angular momentum conservation is violated; hence, only those helicity combinations that conserve angular momentum can yield nonzero values.

For $WW \rightarrow hh$, we separately modify the couplings of the hhh , WWZ , and WWZ vertices and compute $k_M \mathcal{M}^M$. The results are shown in Fig. 14.

For $WW \rightarrow t\bar{t}$, we separately modify the couplings of the tbW , $t\bar{t}Z$, and $t\bar{t}h$ vertices. The results are shown in Fig. 15.

The overall pattern is similar for all three processes. Angular conservation forbids some helicity combinations, giving $k_M \mathcal{M}^M = 0$ automatically, regardless of how the couplings of individual vertices are modified. However, this does not imply that the MWI is valid regardless of the couplings, as there are always some helicity combinations in which a modification of one coupling results in the violation of the MWI.

V. ANOMALOUS COUPLINGS AND SMEFT

Thus far, the anomalous couplings we considered are only instruments to demonstrate the gauge symmetry of related amplitudes. They do not have intrinsic, gauge-invariant, physical meanings. However, there is a scenario in which anomalous couplings can be physical: when those couplings are part of a set of anomalous SM couplings from new physics that respects gauge symmetry. An example that we explore in this section is the SMEFT, which is an effective field theory respecting the SM gauge symmetry. In particular, we discuss two dim-6 SMEFT operators [27–30]: $O_6 = C_6(\Phi^\dagger\Phi)^3$ and $O_\Phi = C_\Phi(\Phi^\dagger\Phi)(\tilde{Q}_L\tilde{\Phi}) + \text{H.c.}$, where Φ is the SM Higgs doublet, and $\tilde{\Phi} \equiv i\sigma^2\Phi^*$. We study how the gauge symmetry is restored in the presence of these operators when the three-point Higgs self-coupling λ_{hhh} and the top Yukawa coupling y_{th} are modified in the $WW \rightarrow hh$ and

Fig. 13. (color online) $k_M \mathcal{M}^M$ for $W^+W^- \rightarrow W^+W^-$ as a function of anomalous overall couplings $\delta_{WW h}$ (a), $\delta_{WW Z}$ (b), and $\delta_{WW W}$ (c). Various helicity combinations are shown.

Fig. 14. (color online) $k_M \mathcal{M}^M$ for $WW \rightarrow hh$ as a function of anomalous overall couplings δ_{hhh} (a), $\delta_{WW h}$ (b), and $\delta_{WW hh}$ (c). Various helicity configurations are shown.

Fig. 15. (color online) $k_M \mathcal{M}^M$ for $WW \rightarrow t\bar{t}$ as a function of anomalous overall couplings δ_{ibW} (a), δ_{ttZ} (b), and δ_{tth} (c). Various helicity combinations are shown.

$WW \rightarrow t\bar{t}$ processes, respectively.

$WW \rightarrow hh$

Adding an SMEFT operator $\mathcal{O}_6 = C_6(\Phi^\dagger\Phi)^3$ into the SM Lagrangian, the hhh and $hh\varphi^+\varphi^-$ couplings are modified to

$$\lambda_{hhh} = \frac{3m_h^2}{v} + 6C_6v^3, \quad \lambda_{hh\varphi^+\varphi^-} = \frac{m_h^2}{v^2} + 6C_6v^2. \quad (19)$$

As the two couplings are modified by the same operator, their deviations from the SM values are related. This relation is further protected by gauge symmetry. Conversely, if we modify one of the couplings alone, say $\lambda_{hhh} = \lambda_{hhh}^{\text{SM}} + \delta_{hhh}$, the gauge symmetry will be broken. To restore gauge symmetry, the other coupling $\lambda_{hh\varphi^+\varphi^-}$ has to be modified by adding

$$\delta_{hh\varphi^+\varphi^-} = \frac{\delta_{hhh}}{v}. \quad (20)$$

Any deviation from the above relation will break gauge symmetry for a process involving both hhh and $hhVV$ couplings, which can be tested with the MWI.

To test the relation (20), we introduce a deviation parameter δ as follows:

Fig. 16. (color online) $k_M \mathcal{M}^M$ for $WW \rightarrow hh$ as a function of δ with different values of δ_{hhh} , serving as a test for gauge symmetry in the presence of the SMEFT operator $\mathcal{O}_6$.

$$\delta_{hh\varphi^+\varphi^-} = \delta_{hhh} v (1 + \delta). \quad (21)$$

Thus, $\delta = 0$ corresponds to the relation (20), which respects gauge symmetry. We consider δ_{hhh} to be 0.2, 0.4, 0.8, and 1. For every δ_{hhh} value, we compute $k_M \mathcal{M}^M$ as a function of δ for the $WW \rightarrow hh$ process with one W polarization vector replaced by the five-component momentum. The results are summarized in Fig. 16. As shown in the figure, $k_M \mathcal{M}^M = 0$ only appears when $\delta = 0$, i.e., when the relation (20) holds. This confirms our argu-

ment that, with an anomalous coupling of λ_{hhh} , gauge symmetry can be restored by adding a proper anomalous coupling of $\lambda_{hh\varphi\varphi}$.

$WW \rightarrow t\bar{t}$

We then focus on the gauge symmetry of the $WW \rightarrow t\bar{t}$ process with the incorporation of the SMEFT operator $\mathcal{O}_{t\Phi} = C_{t\Phi}(\Phi^\dagger\Phi)(\bar{Q}_L t_R \tilde{\Phi}) + \text{H.c.}$. The couplings of tth and $t\varphi\varphi$ are defined as

$$\mathcal{L}_{tth} = -\bar{t}(y_{tth} + iy_{tth}^5\gamma^5)th, \quad (22)$$

$$\mathcal{L}_{t\varphi\varphi} = -\bar{t}(y_{t\varphi\varphi} + iy_{t\varphi\varphi}^5\gamma^5)t\varphi^+\varphi^-. \quad (23)$$

In the SM, the values of these couplings are

$$y_{tth} = \frac{m_t}{v}, \quad y_{tth}^5 = y_{t\varphi\varphi} = y_{t\varphi\varphi}^5 = 0. \quad (24)$$

After the addition of $\mathcal{O}_{t\Phi}$, the couplings are modified to

$$y_{tth} = \frac{m_t}{v} - \frac{v^2}{\sqrt{2}}\text{Re}(C_{t\Phi}), \quad y_{tth}^5 = -\frac{v^2}{\sqrt{2}}\text{Im}(C_{t\Phi}), \quad (25)$$

$$y_{t\varphi\varphi} = -\frac{v^2}{\sqrt{2}}\text{Re}(C_{t\Phi}), \quad y_{t\varphi\varphi}^5 = -\frac{v^2}{\sqrt{2}}\text{Im}(C_{t\Phi}). \quad (26)$$

Based on the above equations, we can obtain the relations between the modifications to these couplings as

$$\delta y_{tth} = \delta y_{t\varphi\varphi} v, \quad \delta y_{tth}^5 = \delta y_{t\varphi\varphi}^5 v. \quad (27)$$

If expressed in left-handed and right-handed couplings,

the Lagrangian terms for the $t\bar{t}h$ and $t\varphi\varphi$ couplings become

$$\begin{aligned} \mathcal{L}_{t\bar{t}h} &= -\bar{t}(y_L P_L + y_R P_R)th, \\ \mathcal{L}_{t\varphi\varphi} &= -\bar{t}(g_L P_L + g_R P_R)t\varphi^+\varphi^-. \end{aligned} \quad (28)$$

The modifications to y_L , y_R , g_L , and g_R are related to $C_{t\Phi}$ as

$$\begin{aligned} \delta y_L &= -\frac{C_{t\Phi}^* v^2}{\sqrt{2}}, & \delta y_R &= -\frac{C_{t\Phi} v^2}{\sqrt{2}}, \\ \delta g_L &= -\frac{C_{t\Phi}^* v}{\sqrt{2}}, & \delta g_R &= -\frac{C_{t\Phi} v}{\sqrt{2}}. \end{aligned} \quad (29)$$

We can observe that they are related to each other by

$$\delta y_{L/R} = \delta g_{L/R} v. \quad (30)$$

Our method of testing the gauge symmetry is similar to that for $WW \rightarrow hh$ with the $\mathcal{O}_6$ operator. Two deviation parameters δ_L and δ_R are introduced as follows:

$$\delta y_{L/R} = \delta g_{L/R} v(1 + \delta_{L/R}). \quad (31)$$

Therefore, $\delta_L = \delta_R = 0$ corresponds to the modifications contributed by the $\mathcal{O}_{t\Phi}$ operator that preserve gauge symmetry. In Figs. 17(a) and 17(b), we show $k_M \mathcal{M}^M$ for $WW \rightarrow t\bar{t}$ as functions of δ_L and δ_R assuming various values of $\text{Re}(\delta_{tth})$ and $\text{Im}(\delta_{tth})$, where δ_{tth} is defined as $\delta_{tth} \equiv C_{t\Phi} v^2 / \sqrt{2}$. As expected, gauge symmetry is restored when the condition in Eq. (30) is satisfied. This demonstrates that an anomalous Yukawa coupling can be counterbalanced by a corresponding $ff\varphi\varphi$ contact vertex, ensuring that the $WW \rightarrow t\bar{t}$ amplitude remains gauge invariant.

Fig. 17. (color online) $k_M \mathcal{M}^M$ for $WW \rightarrow t\bar{t}$ as a function of δ_L (a) and δ_R (b) with different values of $\text{Re}(\delta_{tth})$ and $\text{Im}(\delta_{tth})$, serving as a test for gauge symmetry in the presence of the SMEFT operator $\mathcal{O}_{t\Phi}$.

VI. SUMMARY AND CONCLUSIONS

In this study, we demonstrated that the GE representation of EW interactions, which we had a brief introduction first, has gauge symmetry imprinted in the structure of amplitudes, manifesting in the MWI (1). This approach to gauge symmetry has been rarely studied before, because it involves the vertices of both gauge bosons and Goldstone bosons simultaneously. We numerically studied this important property of EW interactions in the GE representation in several different aspects, including directly testing the MWI, modifying couplings within vertices, and modifying the overall couplings of vertices. Our main conclusion is that there are precise relations within and without the overall vertices, which guarantee the MWI. Any violation of these relations results in the violation of the MWI and gauge symmetry.

By directly testing gauge symmetry on four-point amplitudes, such as $WW \rightarrow t\bar{t}$ and $W^+W^- \rightarrow W^+W^-$, with different helicity combinations, we observed that the full amplitudes always satisfy the MWI after summing over all tree-level diagrams. This result typically involves large cancellations between individual diagrams, similar to unitarity cancellation in the gauge representation.

For testing gauge symmetry on three-point vertices with anomalous couplings, we studied the VVh , $ff'V$, and VVV vertices. We observed that there are precise relations governing the couplings of Goldstone and gauge components for these vertices. We then numerically tested if the MWI still holds when some of the couplings are modified so that those relations are violated. We found that any deviation from those relations by anomalous couplings would violate the MWI.

For testing gauge symmetry on four-point amplitudes with anomalous couplings, we studied $W^+W^+ \rightarrow W^+W^+$, $WW \rightarrow hh$, and $WW \rightarrow t\bar{t}$. We focused on how modifying the overall couplings of individual vertices affects gauge symmetry. Our results are similar to those for three-point vertices: gauge symmetry is manifested as precise relations between couplings, and modifying couplings to violate those relations also results in violating the MWI.

After studying the gauge symmetry of the SM, we studied the effective operators in the SMEFT, specifically the O_6 operator, which modifies the Higgs self-couplings, and the $O_{t\Phi}$ operator, which modifies the top Yukawa coupling. We observed that the operators modify both the couplings mentioned and the related Goldstone couplings, giving relations between the couplings involving C_6 and $C_{t\Phi}$, respectively. Numerically testing the MWI indicates that gauge symmetry is preserved as long as all the related couplings are modified in accordance with those relations. On the other hand, if those relations are violated, gauge symmetry would be broken. Similar to the SM, our results for these SMEFT operators demonstrate that not only the gauge components but also the Goldstone components are crucial for maintaining the gauge invariance of the theory. This is also the reason why, gauge cancellation in the unitary gauge, in which there is no Goldstone mode, appears to be ad hoc without an apparent physical mechanism.

We believe that this paper contributes to a deeper understanding of EW interactions and massive gauge theory in general. In addition, it provides a convenient method of checking the self-consistency of EW interactions in the GE representation.

Thus far, the five-component formalism has been only systematically implemented in HELAS for the tree-level Feynman rules of the SM. Moreover, for the purpose of this study, we included the dim-6 operators O_6 and $O_{t\Phi}$ in HELAS. However, the majority of the SMEFT operators remain to be incorporated. This limits the utility of our method and calls for more progress in this aspect. In Ref. [12], a general method for automatically implementing the five-component framework has been proposed recently; which, we hope could help apply our method to more general theories.
