1 Introduction

The interacting boson model (IBM) has proven to be extremely successful in the description of both the collective valence shell [1] and multi-particle-hole [2–4] excitations in nuclei. Most noticeably, the IBM Hamiltonian without configuration mixing can be solved analytically in $U(5)$ (vibrational), $O(6)$ ($\gamma$-unstable), and $SU(3)$ (rotational) limits [1], as well as in the $U(5)–O(6)$ transitional case [5]. In contrast, configuration mixing due to multi-particle-hole excitations was considered to gain an understanding of the shape coexistence phenomena by assuming different symmetry limits of the IBM for different configurations [6–12], which has proven to be successful in describing intruder states and shape coexistence phenomena in near closed shell nuclei, typically those around proton numbers $Z~50$ and $Z~82$ [2–4]. Recently, the intruder configuration mixing schemes with $2n$-particle and $2n$-hole configurations from $n = 0$ up to $n \to \infty$ in the $U(5)$ (vibrational) and the $O(6)$ ($\gamma$-unstable) limits of the IBM-I were proposed [13, 14], whose simple Hamiltonians, suitable to describe the intruder and normal configuration mixing, prove to be exactly solvable based on the $SU(1,1)$ coherent states.

The configuration mixing schemes in the IBM [2–4] can be considered in both IBM-II and IBM-I with no distinction between neutron-type and proton-type bosons, as shown in [7–10, 13–16]. In this study, we demonstrate that the $U(5)\leftrightarrow O(6)$ transitional Hamiltonian of the IBM-I with two-particle and two-hole configuration mixing is also exactly solvable based on the Bethe ansatz approach. The results of $N = 2$ and $N = 4$ cases are considered as examples to demonstrate the feature of the solution. To apply this theory, the model is employed to fit some low-lying level energies and $B(E2)$ ratios of $^{108}\text{Cd}$.

2 Model and its exact solution

The Hamiltonian of the $U(5)–O(6)$ transitional description in the IBM-I with two-particle and two-hole configuration mixing is expressed as [2–4]

$$\hat{H} = \hat{P}_N \hat{H}_0^{(0)} \hat{P}_N + \hat{P}_{N+2} \hat{H}_0^{(2)} \hat{P}_{N+2} + \hat{P} \hat{H}_{\text{mix}} \hat{P},$$

(1)

where $\hat{P}_N$ and $\hat{P}$ are the projection operators, where $\hat{P}_N$ projects to the $N$-boson subspace, whereas $\hat{P}$ projects to the subspace with $N$ and $N + 2$ bosons,

$$\hat{H}_0^{(i)} = a_s^{(i)} S_s^+ S_s^- + a_d^{(i)} S_d^+ S_d^- + g^{(i)} S^+ S^-$$

(2)

For $i = 1$ and 2, these are the $U(5) – O(6)$ transitional Hamiltonians [5], and

$$\hat{H}_{\text{mix}} = g_s (S_s^+ S_s^-) + g_d (S_d^+ S_d^-)$$

(3)
is the two-configuration mixing term. Here, \( S^+ = S^+_s - S^+_d \) with 
\[ S^+_s = \frac{1}{2} s^{12} \] and 
\[ S^+_d = \frac{1}{2} d^{12} \cdot d^1 = \frac{1}{2} \sum_{\mu} \langle \mu | -\gamma \delta d_{\mu} d_{\mu} \rangle, \]
where \( s^{12} \) (s) and \( d_{\mu} \) (d) are the creation (annihilation) operators of 
- and \( d \)-bosons, respectively, \( S^- = (S^+_s)^\dagger \) for \( \rho = s \) or \( d \), 
\( S^0_s = \frac{1}{2} (\hat{s}_s + \frac{1}{2}) \) and \( S^0_d = \frac{1}{2} (\hat{s}_d + \frac{1}{2}) \), respectively, with 
\( \hat{s}_s = s^s s^s \) and \( \hat{s}_d = s^d d^d \). The \( \sum_{\mu} \langle \mu | \delta d_{\mu} d_{\mu} \rangle \) represent the angular 
momentum quantum number, \( M \) is the quantum number of the third component of the 
angular momentum, and \( \eta \) is an additional quantum number required to distinguish different states with the same \( L \).
Moreover, the two sets of operators \( \{ S^+_{\rho}, S^0_{\rho} \} \) (\( \rho = s, d \)) that are two copies of the \( SU(1,1) \) algebra, satisfy the commutation relations 
\[ [S^0_{\rho}, S^+_{\rho}] = \pm \delta_{\rho\rho} S^+_{\rho}, [S^-_{\rho}, S^+_{\rho}] = 2\delta_{\rho\rho} S^0_{\rho}. \] (4)
Equivalently, for a given \( N, n_d, \nu_d, \eta, L, \) and \( M \), the orthonormalized basis vectors \( |N n_d \nu_d \eta \rangle \) can also be expressed as those of \( SU(1,1) \otimes SU(1,1) \) with
\[ |N, \xi \nu_d \eta \rangle \rangle LM = (-1)^{\xi} N(S^0_{\xi})^{\langle N+2, \xi + 1 \rangle} (S^+_{\xi})^{\langle N+2, \xi + 1 \rangle} |\nu_d \eta \rangle LM, \]
where \( n_d = 2\xi + \nu_d \) and \( \xi = 0, 1, 2, \cdots, \frac{1}{2} (N - \nu_d - \nu_s) \) with \( \nu_s = 0 \) or 1, where the normalization constant
\[ N = \left( \frac{2^{N-\nu_d-\nu_s-2}(2r+3)!!}{\xi!(N-\nu_d-\nu_s-2)!2^{2r+3}!!} \right)^{\frac{1}{2}}. \] (6)
The conventional phase factor \((-1)^{\xi}\) shown in Eq. (5) for \( SU(1,1) \) is adopted, which is consistent with the generalization of pairing operator \( S^\pm = S^+_{\xi} - S^-_{\xi} \) used in Eq. (2). The matrix representations of \( SU(1,1) \otimes SU(1,1) \) under the basis vectors (5) are given by

\[ S^\pm |N, \xi \nu_d \eta \rangle LM = \frac{1}{2} \sqrt{-2(2\xi + 2)(2\nu_d + 2\xi + 5)} |N + 2, \xi + 1, \nu_d \eta \rangle LM, \]
\[ S^\pm |N, \xi \nu_d \eta \rangle LM = \frac{1}{2} \sqrt{2(2\nu_d + 2\xi + 3)} |N - 2, \xi - 1, \nu_d \eta \rangle LM, \]
\[ S^0 |N, \xi \nu_d \eta \rangle LM = \frac{1}{2} (\nu_d + 2\xi + 2) |N, \xi \nu_d \eta \rangle LM, \] (7)

and

\[ \langle \xi \nu_d ; \nu_d \eta | \rangle LM = \frac{1}{2} \sqrt{(N - \nu_d - 2\xi) (N - \nu_d - 2\xi - 1)} |N + 2, \xi, \nu_d \eta \rangle LM, \]
\[ \langle \xi \nu_d ; \nu_d \eta | \rangle LM = \frac{1}{2} \sqrt{(N - \nu_d - 2\xi - \eta) (N - \nu_d - 2\xi - \eta - 1)} |N - 2, \xi, \nu_d \eta \rangle LM, \]
\[ \langle \xi \nu_d ; \nu_d \eta | \rangle LM = \frac{1}{2} (N - \nu_d - 2\xi - 1) |N, \xi, \nu_d \eta \rangle LM. \] (8)

The eigenstate of Eq. (1) can be written as

\[ |\xi \nu_d ; \nu_d \eta \rangle LM = \sum_{\rho = 1}^{k} S^\pm |\rho \rangle \sum_{\mu = 1}^{\rho + 1} S^0_{\mu} |\nu_d \eta \rangle LM, \]
\[ + \sum_{\rho = 1}^{k+1} S^\pm |\rho \rangle \sum_{\mu = 1}^{\rho + 1} S^0_{\mu} |\nu_d \eta \rangle LM, \] (9)
where \( a_{\rho \nu_d \eta}^{(C)} \) and \( b_{\rho \nu_d \eta}^{(C)} \) in general, are complex numbers to be determined, \( \xi \) labels the \( \xi \)-th set of solution 
\[ s_1^{(C)}, \cdots, s_{\xi}^{(C)}, \nu_1^{(C)}, \cdots, \nu_{\xi}^{(C)} \]}, \( a_{\xi \nu_d \eta}^{(C)} \) and \( b_{\xi \nu_d \eta}^{(C)} \) are the boson pairing vacuum state satisfying \( S^\pm |\nu_d \eta \rangle LM \)
for \( \rho = s \) and \( d \), in which \( \nu_s = 0 \) or 1, and
\[ S^\pm(x) = x S^+_s + S^+_d, \]
which is equivalent to the form used in Ref. [5] with a linear transformation for \( x \), where \( x \) is the spectral parameter to be determined. Using the commutation relations (4), one can directly verify that

\[ [g_s S^+_s + g_d S^+_d, S^\pm(x)] = 2g_s S^0_d + 2g_d S^0_s, \]
\[ [[g_s S^+_s + g_d S^+_d, S^\pm(x)], S^\pm(y)] = \frac{2g_s (x - y) S^+(x)}{y - x} - \frac{2g_d (x - y) S^+(y)}{y - x}. \] (12)
\[ [\alpha_s S^0_x + \alpha_d S^0_d, S^+ (x)] = \frac{(\alpha_s - \alpha_d)x}{1 + x} S^+ + \frac{\alpha_s x + \alpha_d}{1 + x} S^+ (x), \] (13)

\[ [S^-, S^+ (x)] = 2x S^0_d - 2 S^0_d. \] (14)

\[ [[S^-, S^+ (x)], S^+ (y)] = \frac{2y(1 + x)}{x - y} S^+ (x) + \frac{2x(1 + y)}{y - x} S^+ (y). \] (15)

There are also useful identities:

\[ S^+ (y) S^+(x) = \sum_{k=1}^{\infty} \prod_{j=1}^{k} (x_j - y_j) \prod_{j=1}^{k} S^+(x_j), \] (17)

or

\[ \prod_{j=1}^{k} S^+ (y_j) = \sum_{\rho(\sigma)} \prod_{j=1}^{k} (x_j - y_j) \prod_{j=1}^{k} S^+ (x_j), \] (18)

which can be proven using a mathematical induction on \( k \), as \( S^+ (x) \) and \( S^+ (y) \) are binomials of \( S^+_i \) and \( S^+_d \). Using Eq. (17) with \( x_{k+1} = -1 \), we also have

\[ \prod_{j=1}^{k} S^+ (y_j) = \sum_{\rho(\sigma)} \prod_{j=1}^{k} (1 + x_j) \prod_{j=1}^{k} S^+ (x_j) - \sum_{\rho(\sigma)} \prod_{j=1}^{k} (x_j - x_{k+1} - 1) S^+ \prod_{j=1}^{k} S^+ (x_j). \] (19)

Similar to the \( O(5) - O(6) \) case shown in Ref. [5], using the above commutation relations and identities, one can verify that

\[ P_N \hat{H}_1^{(1)} P_N \prod_{j=1}^{k} S^+ (x_j) | v_\sigma; v_d \eta L M \rangle = \sum_{j=1}^{k} \left( \alpha_s^{(1)} \frac{x_j + \alpha_d^{(1)}}{1 + x_j} + \alpha_d^{(1)} \frac{s_j + \alpha_d^{(1)} S_0^+}{1 + x_j} \right) \prod_{j=1}^{k} S^+ (x_j) | v_\sigma; v_d \eta L M \rangle \]

\[ + \sum_{j=1}^{k} \left( \alpha_s^{(1)} \frac{x_j + \alpha_d^{(1)}}{1 + x_j} + \alpha_d^{(1)} \frac{s_j + \alpha_d^{(1)} S_0^+}{1 + x_j} \right) \prod_{j=1}^{k} S^+ (x_j) | v_\sigma; v_d \eta L M \rangle, \] (20)

\[ P_{N+2} \hat{H}_1^{(1)} P_{N+2} \prod_{j=1}^{k} S^+ (y_j) | v_\sigma; v_d \eta L M \rangle = \sum_{j=1}^{k} \left( \alpha_s^{(2)} \frac{y_j + \alpha_d^{(2)}}{1 + y_j} + \alpha_d^{(2)} \frac{s_j + \alpha_d^{(2)} S_0^+}{1 + y_j} \right) \prod_{j=1}^{k} S^+ (y_j) | v_\sigma; v_d \eta L M \rangle \]

\[ + \sum_{j=1}^{k} \left( \alpha_s^{(2)} \frac{y_j + \alpha_d^{(2)}}{1 + y_j} + \alpha_d^{(2)} \frac{s_j + \alpha_d^{(2)} S_0^+}{1 + y_j} \right) \prod_{j=1}^{k} S^+ (y_j) | v_\sigma; v_d \eta L M \rangle, \] (21)

\[ P \hat{H}_{\text{min}} P \prod_{j=1}^{k} S^+ (x_j) | v_\sigma; v_d \eta L M \rangle = \sum_{j=1}^{k} \left( \alpha_s \frac{y_j + \alpha_d}{1 + y_j} + \alpha_d \frac{s_j + \alpha_d S_0^+}{1 + y_j} \right) \prod_{j=1}^{k} S^+ (x_j) | v_\sigma; v_d \eta L M \rangle \]

\[ + \sum_{j=1}^{k} \left( \alpha_s \frac{y_j + \alpha_d}{1 + y_j} + \alpha_d \frac{s_j + \alpha_d S_0^+}{1 + y_j} \right) \prod_{j=1}^{k} S^+ (x_j) | v_\sigma; v_d \eta L M \rangle, \] (22)

where the identities (18) and (12) for \( y_j \) within the summation over \( j \) are applied,

\[ P \hat{H}_{\text{min}} P \prod_{j=1}^{k} S^+ (y_j) | v_\sigma; v_d \eta L M \rangle = (g_s S^+_s + g_d S^+_d) \prod_{j=1}^{k} S^+ (y_j) | v_\sigma; v_d \eta L M \rangle \]

\[ = \sum_{j=1}^{k} \left( 2g_s y_j \bar{S}_0^+ + 2g_d \bar{S}_0^+ \right) \prod_{j=1}^{k} S^+ (y_j) | v_\sigma; v_d \eta L M \rangle \]

\[ = \sum_{j=1}^{k} \left( 2g_s y_j \bar{S}_0^+ + 2g_d \bar{S}_0^+ \right) \prod_{j=1}^{k} S^+ (y_j) | v_\sigma; v_d \eta L M \rangle, \] (23)

where the identity (19) is used.

Therefore, the eigen-equation

\[ \hat{H}_{\text{min}} | v_\sigma; v_d \eta L M \rangle = E_{v_\sigma; v_d \eta L M} | v_\sigma; v_d \eta L M \rangle \] (24)

is fulfilled if and only if
\[ a_{v',v;\mu}^{(C)} \left( \frac{\alpha_s^{(1)} - \alpha_d^{(1)}}{1 + x_j^{(1)}} + g^{(1)}(2x_j^{(1)} \overline{S_0} - 2S_0 d) + g^{(1)} \sum_{j(x_j)} x_j^{(1)}(x_j^{(1)} + 1) \right) \]
\[ - \mathbf{b}_{v',v;\mu}^{(C)} \sum_{i=1}^{k+1} \left( 2g_s x_i^{(C)} \overline{S_0} + 2gd \overline{S_0} + \sum_{j(x_j)} 2x_j^{(C)} (g_s x_j^{(C)} - gd) \right) + \prod_{i(x_i)} \left( x_i^{(C)} - y_i^{(C)} \right) = 0 \quad \text{for } j = 1, 2, \cdots, k, \quad (25) \]

\[ b_{v',v;\mu}^{(C)} \left( \frac{\alpha_s^{(2)} - \alpha_d^{(2)}}{1 + y_j^{(2)}} + g^{(2)}(2y_j^{(2)} \overline{S_0} - 2S_0 d) + g^{(2)} \sum_{j(x_j)} 2y_j^{(2)}(y_j^{(2)} + 1) \right) + \alpha_{v',v;\mu}^{(C)} \prod_{i(x_i)} \left( y_i^{(C)} - y_i^{(C)} \right) = 0 \quad \text{for } j = 1, 2, \cdots, k + 1, \quad (26) \]

and

\[ a_{v',v;\mu}^{(C)} \left( E_{v',v;\mu}^{(C)} - \sum_{j(x_j)} \frac{\alpha_s^{(1)} x_j^{(1)} + \alpha_d^{(1)}}{1 + x_j^{(1)}} - \alpha_s^{(1)} \overline{S_0} - \alpha_d^{(1)} \overline{S_0} \right) \]
\[ = \mathbf{b}_{v',v;\mu}^{(C)} \sum_{j(x_j)} \left( 2g_s y_j^{(C)} \overline{S_0} + 2gd \overline{S_0} + \sum_{j(x_j)} 2y_j^{(C)} (g_s y_j^{(C)} - gd) \right) + \prod_{j(x_j)} \left( y_j^{(C)} - y_j^{(C)} \right) \]
\[ D = \sum_{j(x_j)} \frac{\alpha_s^{(2)} y_j^{(2)} + \alpha_d^{(2)}}{1 + y_j^{(2)}} + \alpha_s^{(2)} \overline{S_0} + \alpha_d^{(2)} \overline{S_0} \quad (27) \]

Eqs. (27) and (28) are nothing but the eigen-equation
\[ \begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} a_{v',v;\mu}^{(C)} \\ b_{v',v;\mu}^{(C)} \end{pmatrix} = E_{v',v;\mu}^{(C)} \begin{pmatrix} a_{v',v;\mu}^{(C)} \\ b_{v',v;\mu}^{(C)} \end{pmatrix} \quad (29) \]

with
\[ A = \sum_{j(x_j)} \frac{\alpha_s^{(1)} x_j^{(1)} + \alpha_d^{(1)}}{1 + x_j^{(1)}} + \alpha_s^{(1)} \overline{S_0} + \alpha_d^{(1)} \overline{S_0}, \]
\[ B = \sum_{j(x_j)} \left( 2g_s y_j^{(C)} \overline{S_0} + 2gd \overline{S_0} + \sum_{j(x_j)} 2y_j^{(C)} (g_s y_j^{(C)} - gd) \right) \times \prod_{j(x_j)} \left( y_j^{(C)} - y_j^{(C)} \right) \]
\[ C = \sum_{j(x_j)} \prod_{j(x_j)} \left( y_j^{(C)} - y_j^{(C)} \right) \]
\[ D = \sum_{j(x_j)} \frac{\alpha_s^{(2)} y_j^{(2)} + \alpha_d^{(2)}}{1 + y_j^{(2)}} + \alpha_s^{(2)} \overline{S_0} + \alpha_d^{(2)} \overline{S_0} \quad (30) \]

Thus, \( a_{v',v;\mu}^{(C)}, b_{v',v;\mu}^{(C)}, \) and \( E_{v',v;\mu}^{(C)} \) can be expressed in terms of the variables \( \{x_j^{(1)}\} (j = 1, 2, \cdots, k) \) and \( \{y_j^{(2)}\} (j = 1, 2, \cdots, k + 1) \). Once \( a_{v',v;\mu}^{(C)}, b_{v',v;\mu}^{(C)}, \) and \( E_{v',v;\mu}^{(C)} \) are expressed in terms of \( A, B, C, \) and \( D \) shown in Eq. (30), the variables \( \{x_j^{(1)}\} (j = 1, 2, \cdots, k) \) and \( \{y_j^{(2)}\} (j = 1, 2, \cdots, k + 1) \) are determined by Eqs. (25) and (26). It is evident that Eq. (25)–(28) become

\[ (\alpha_s^{(1)} - \alpha_d^{(1)}) x_j^{(1)} + g^{(1)}(2x_j^{(1)} \overline{S_0} - 2S_0 d) + g^{(1)} \sum_{j(x_j)} x_j^{(1)}(x_j^{(1)} + 1) = 0 \quad \text{for } j = 1, 2, \cdots, k, \quad (31) \]

\[ E_{v',v;\mu}^{(C)} = \sum_{j(x_j)} \frac{\alpha_s^{(1)} x_j^{(1)} + \alpha_d^{(1)}}{1 + x_j^{(1)}} + \alpha_s^{(1)} \overline{S_0} + \alpha_d^{(1)} \overline{S_0}, \quad a_{v',v;\mu}^{(C)} = 0, \quad \beta_{v',v;\mu}^{(C)} = 0, \quad (32) \]

or

\[ (\alpha_s^{(2)} - \alpha_d^{(2)}) y_j^{(2)} + g^{(2)}(2y_j^{(2)} \overline{S_0} - 2S_0 d) + g^{(2)} \sum_{j(x_j)} 2y_j^{(2)}(y_j^{(2)} + 1) = 0 \quad \text{for } j = 1, 2, \cdots, k + 1, \quad (33) \]

\[ E_{v',v;\mu}^{(C)} = \sum_{j(x_j)} \frac{\alpha_s^{(2)} y_j^{(2)} + \alpha_d^{(2)}}{1 + y_j^{(2)}} + \alpha_s^{(2)} \overline{S_0} + \alpha_d^{(2)} \overline{S_0}, \quad a_{v',v;\mu}^{(C)} = 0, \quad \beta_{v',v;\mu}^{(C)} = 0, \quad (34) \]
when \( g_s = g_d = 0 \) without configuration mixing, which are the Bethe ansatz equations and the corresponding eigenenergy of the \( U(5) - O(6) \) transitional case for the \( \bar{N} \)-boson normal states and the \( N + 2 \)-boson intruder states, respectively.

Similar to the results shown in Ref. [18], there are extended Heine-Stieltjes polynomials \( y^{(i)}(x) \) related to Eqs. (31) and (33) satisfying

\[
F(x) \frac{d^2 y^{(i)}(x)}{dx^2} + G^{(i)}(x) \frac{dy^{(i)}(x)}{dx} + V^{(i)}(x) y^{(i)}(x) = 0
\]

for \( i = 1 \) or \( i = 2 \), where \( F(x) = x(1 + x)^2 \),

\[
G^{(i)}(x)/F(x) = \frac{1}{1 + x} \left( \frac{25\sqrt{5}}{x} - 2\sqrt{5} \right) + \frac{a^{(i)}_d - a^{(i)}_s}{e^{(i)}(1 + x)} - 2k + 2 \tag{36}
\]

and \( V^{(i)}(x) \) is a linear function of \( x \) determined by Eq. (35). The roots of Eqs. (31) or (33) are zeros of \( y^{(1)}(x) \) or \( y^{(2)}(x) \). Hence, the polynomial approach shown in Ref. [18] applies to this case as well, which can be used to obtain a solution of Eqs. (31) and (33) when there is no configuration mixing with \( g_s = g_d = 0 \).

It is evident that the pairing operators \( \prod_{\mu=1}^{k} S^+(x^{(C)}_{\mu}) \) and \( \prod_{\mu=1}^{k+1} S^+(y^{(C)}_{\mu}) \) used in Eq. (9) are symmetric with respect to any permutation among \( \{x^{(1)}_1, \ldots, x^{(1)}_k\} \) and \( \{y^{(1)}_1, \ldots, y^{(1)}_{k+1}\} \). Therefore, there are \( k(k+1)! \) identical roots of Eqs. (25) and (26), where only one is needed to construct the eigenstate (9). Once the \( \zeta \)-th root \( \{x^{(1)}_1, \ldots, x^{(1)}_k\} \) and \( \{y^{(1)}_1, \ldots, y^{(1)}_{k+1}\} \) of Eqs. (25) and (26) are obtained, the pairing operators \( \prod_{\mu=1}^{k} S^+(x^{(C)}_{\mu}) \) and \( \prod_{\mu=1}^{k+1} S^+(y^{(C)}_{\mu}) \) in Eq. (9) can be expressed as

\[
\prod_{\mu=1}^{k} S^+(x^{(C)}_{\mu}) = \sum_{\mu=0}^{k} S^{(0)}(x^{(1)}_1, \ldots, x^{(1)}_k) S^\mu_d S^{k-\mu}_d,
\]

\[
\prod_{\mu=1}^{k+1} S^+(y^{(C)}_{\mu}) = \sum_{\mu=0}^{k+1} S^{(0)}(y^{(1)}_1, \ldots, y^{(1)}_{k+1}) S^\mu_d S^{k+1-\mu}_d \tag{37}
\]

where \( S^{(0)}(x^{(1)}_1, \ldots, x^{(1)}_k) = \sum_{\mu=0}^{k} \prod_{\mu=1}^{k} x^{(C)}_\mu \) starting with \( S^{(0)}(x^{(1)}_1, \ldots, x^{(1)}_k) = 1 \), and similarly for \( S^{(0)}(y^{(1)}_1, \ldots, y^{(1)}_{k+1}) \), is the \( \mu \)-th elementary symmetric polynomial of the \( k \) root-components \( \{x^{(1)}_1, \ldots, x^{(1)}_k\} \) of Eq. (25), which is helpful for calculating matrix elements of physical quantities of the system.

3 Exemplified solution

The solution of Eq. (1) can be derived using the extended Heine-Stieltjes polynomial approach shown in Eq. (35). When there is no configuration mixing with \( g_s = g_d = 0 \), the roots \( \{y^{(1)}_{01}, \ldots, y^{(1)}_{0k}\} \) and \( \{y^{(1)}_{01}, \ldots, y^{(1)}_{0k+1}\} \) can be obtained, where the total number of roots is \( 2k + 3 \), for which \( N = 2k + v_d + v_s \) for the allowed angular momentum quantum number \( L \) determined by the reduction rule \( (v_d, v_s) = L \) of \( O(5)\!\!-O(3) \). Then, for small values of \( g_s \) and \( g_d \), the root \( \{y^{(1)}_1, \ldots, y^{(1)}_k\} \) and \( \{y^{(1)}_1, \ldots, y^{(1)}_{k+1}\} \) of Eqs. (25) and (26) for the given \( \zeta \) is obtained using \( \{y^{(1)}_{01}, \ldots, y^{(1)}_{0k}\} \) and \( \{y^{(1)}_{01}, \ldots, y^{(1)}_{0k+1}\} \) as the initial root to determine the solution. Repeating this procedure, one can identify \( 2k + 3 \) sets of the roots for any real values \( g_s \) and \( g_d \). Notably, all roots are real when \( g_s = g_d = 0 \), which is a common feature of the general \( SU(1,1) \) Gaudin models without previous study of the configuration mixing [5, 17, 18]. However, for \( g_s \neq 0 \) and \( g_d \neq 0 \), complex roots occur in the middle part of the spectrum when the mixing of the \( \bar{N} \)-boson and \( N + 2 \)-boson configurations is relatively strong, particularly when \( k \) is large, which is common when the configuration mixing strengths \( g_s \) and \( g_d \) become sufficiently large. Because \(-1 \) and \( 0 \) are singular points of Eqs. (25) and (26), the real part of the root components lies in the union \((-\infty, -1] \cup [-1, 0] \cup [0, \infty) \), where no pair of the root components is the same. In fact, similar to the solution of the pairing model [19], all root components are always symmetric with respect to the real axis on the complex plane; namely, if a root component is complex, the conjugate root component must be involved.

To demonstrate the feature of the solution, we consider an example with \( \alpha^{(1)}_s = 0, \alpha^{(1)}_d = 0.3 \) MeV, \( \alpha^{(2)}_s = -0.5 \) MeV, \( \alpha^{(2)}_d = 1.5 \) MeV, \( \alpha^{(2)}_s = 1.8 \) MeV, \( \alpha^{(2)}_d = -0.2 \) MeV, and \( g_s = g_d = 0.2 \) MeV. Only \( v_s = v_d = 0 \) is exemplified in the following. As shown in Table 1, all roots in this case are real for \( N = 2 \). It is obvious that the first two roots mainly lie in the \( N = 2 \) configuration, as indicated by the small \( \beta^{(1)}/\alpha^{(1)} \) values, whereas the last three roots mainly lie in the \( N + 2 = 4 \) configuration, as indicated by the relatively larger \( \beta^{(2)}/\alpha^{(2)} \) values. For \( N = 4 \), the pattern of the roots is similar. The first three roots mainly lie in the \( N = 4 \) configuration, whereas the last four roots mainly lie in the \( N + 2 = 6 \) configuration. As shown in Table 2, the third root components with \( y^{(3)} = y^{(2)} \) and the fifth root components with \( x^{(5)} = x^{(2)} \) are complex in this case. In fact, with further increasing of the configuration mixing strengths \( g_s \) and \( g_d \), complex roots also occur for the \( N = 2 \) case. Because the two roots with relatively small \( \beta^{(1)}/\alpha^{(1)} \) values mainly lie in the \( N = 2 \) configuration, whereas the three roots with relatively larger \( \beta^{(2)}/\alpha^{(2)} \) values mainly lie in the \( N + 2 = 4 \) configuration, the root of the ground state in this case becomes complex when \( g_s \) or \( g_d \) become sufficiently large. For example, if we keep other parameters the same as those shown in Table 1, the root of the ground state becomes complex when \( g_s = g_d > 6.06492 \) MeV with \( y^{(1)}_1 = 0.56635, y^{(1)}_2 = 0.72673 + 0.00027i, y^{(1)}_3 = 0.72673 - 0.00027i, \beta^{(1)} = -0.3067, \beta^{(2)} = 0.3067, \beta^{(3)} = 0.3067 \).
Table 1. Roots of Eqs. (25) and (26), ratio $\beta^{(i)}/\sigma^{(i)}$ used in eigen-state (9) and corresponding eigen-energy $E^{(i)}$ (in MeV) of the model for $N = 2$, where the parameters of Eq. (1) are considered as $\alpha^{(1)} = 0$, $\alpha^{(2)} = 0.3$ MeV, $g^{(1)} = -0.5$ MeV, $\alpha^{(3)} = 1.5$ MeV, $\alpha^{(4)} = 1.8$ MeV, $g^{(3)} = -0.2$ MeV, and $g_s = g_d = 0.2$ MeV.

Table 2. Same as Table 1, but for $N = 4$, where $I = \sqrt[4]{I}$.

$E^{(1)} = -14.8053$ MeV for $g_s = g_d = 6.06492$ MeV. Therefore, the complex solution is likely to occur when the experiment configuration is sufficiently strong.

To apply this theory, the Hamiltonian (1) is employed to describe the low-lying spectrum of $^{108}$Cd with $N = 6$ bosons, where the term $H_E = fL \cdot L$ is added to Eq. (1) to lift the degeneracy of the levels with the same energy but different angular momentum quantum numbers.

The $E_2$ operator is chosen as

$$T_p(E_2) = q_2 P_n (d'_s s + d'_d d) P_n + q'_2 P_{n+2} (d'_s s + d'_d d) P_{n+2}$$

(38)

with which the $B(E_2)$ values are given by

$$B(E_2; L_i \rightarrow L_f) = \frac{2L_f + 1}{2L_i + 1} \frac{1}{|\langle \xi^{(i)}; v'_2 \eta' d'_2 | T(E_2)| \xi^{(i)}; v_2 \eta d L_i \rangle|^2}$$.

(39)

where $q_2$ and $q'_2$ are effective charge parameters of the normal and intruder configurations, respectively, and the reduced matrix element is defined in terms of the CG coefficient, such that $\langle \xi, v'_2 \eta' d'_2 | T(E_2)| \xi, v_2 \eta d L_i \rangle = \delta_{\xi, \xi} \delta_{v'_2, v_2} \delta_{d'_2, d} \delta_{L_i, L}$, with unit identity operator $I$.

Similar to that in Ref. [13], the level energies up to the three-phonon states in the normal bands and the intruder states $0^+_1(i), 2^+_1(i)$, and $4^+_1(i)$ of $^{108}$Cd deduced in Ref. [20] are considered. The model parameters are produced by a best global fit to the experimental level energy alone, where we obtain $\alpha^{(1)} = 0$, $\alpha^{(2)} = 1.261$ MeV, $g^{(1)} = -1$ keV, $\alpha^{(3)} = 300$ keV, $\alpha^{(4)} = 1.416$ MeV, $g^{(2)} = -51$ keV, $g_s = 220$ keV, $g_d = 200$ keV, $f = 5$ keV, and $q'_2/q_2 = -0.38$. Then, the experimentally measured $B(E_2)$ ratios, $R(L_i \rightarrow L_f) = B(E_2; L_i \rightarrow L_f)/B(E_2; 2^+_1 \rightarrow 0^+_1)$, provided in Ref. [20] are fitted by only adjusting the ratio $q'_2/q_2$. The fitted low-lying level energies and $B(E_2)$ ratios are shown in Table 3, where the corresponding results of the 2n-particle and 2n-hole configuration mixing from $n = 0$ to $n \rightarrow \infty$ in the $U(5)$ limit of the IBM (CM5) [13] are likewise provided. The ratio $q'_2/q_2 = 2.9$ is mainly determined according to the lower limit of the experimental ratio $R(4^+_1(i) \rightarrow 2^+_1(i))$. Regarding the level energies, the $U(5) - O(6)$ transitional description is slightly better than the CM5, whereas the $B(E_2)$ ratios generated in the two models are quite the same for the transitions among normal states. However, although the $E_2$ decays out of the intruder band are still weaker [20], the $B(E_2)$ ratio $R(2^+_1(i) \rightarrow 0^+_1(i))$ and those for the transitions from the intruder states to the normal states predicted in this model are far larger than those of the CM5, as shown in III. Arguably, these values can be reduced when configuration mixing with $N + 2n$ bosons for $n > 2$ is considered. Because the $E_2$ operator is simply selected as the generator of $O(6)$, as shown in Eq. (38) and in the CM5 case [13], the $E_2$ selection rule is similar to those given in the $U(5)$ or the $O(6)$ limit without configuration mixing, which are given by $\Delta N_{vd} = \pm 1$. Therefore, the $\Delta N_{vd} = \pm 2$ transitions, such as $B(E_2; 2^+_2 \rightarrow 0^+_2)$, and the $\Delta N_{vd} = 0$ transitions, such as $B(E_2; 2^+_1(i) \rightarrow 2^+_1)$ and $B(E_2; 4^+_1(i) \rightarrow 4^+_1)$, are consistently zero. To improve the theory, the $O(6)$ symmetry breaking terms, such as the $(d'_s d'_d)$ term, which allows $\Delta N_{vd} = 2$ transitions, must be added in the $E_2$ operator. Alternatively, high order interactions, such as those
Table 3. Some low-lying level energies and $B(E2)$ ratios $R(L_i \to L_f) = B(E2; L_i \to L_f)/B(E2; 2^+_1 \to 0^+_2)$ of $^{108}\text{Cd}$, where $i$ indicates that the corresponding spin assignment is not fully confirmed. The spin of both $0^+_2(i)$ and $0^+_1(i)$ states was assigned with (0°, 1°, 2°), as shown in Ref. [21]. Model parameters are considered as $\alpha^{(1)}_i = 0$, $\alpha^{(1)}_g = 1.261\text{ MeV}$, $g^{(i)} = -1\text{ keV}$, $\alpha^{(2)}_o = 300\text{ keV}$, $\alpha^{(2)}_g = 1.416\text{ MeV}$, $g^{(2)} = -51\text{ keV}$, $g = 220\text{ keV}$, $gd = 200\text{ keV}$, $f = 5\text{ keV}$, and $q^2 / q_2 = 2.9$.

4 Summary

In this study, we demonstrate that the $U(5)-O(6)$ transitional Hamiltonian of the interacting boson model with two-particle and two-hole configuration mixing is exactly solvable. An exact solution is derived based on the Bethe ansatz approach, where the Bethe ansatz equations are provided to determine the eigenstates and the corresponding eigen-energies. The solution features are numerically exemplified by the $N = 2$ and $N = 4$ cases. As an example of application, some low-lying level energies and $B(E2)$ ratios of $^{108}\text{Cd}$ are fitted and compared with the corresponding experimental data.

Because the solution of the Hamiltonian without configuration mixing can be easily derived using the extended Heine-Stieltjes polynomials, the roots of the Bethe ansatz equations for cases with small mixing parameters are approximately found using the roots of the equations without configuration mixing as the initial values. Therefore, a progressive approach can be established to obtain the solution of the model with arbitrary mixing parameters. Although the solution is only demonstrated for the $N \oplus (N+2)$ configuration mixing, it is expected that the model with 2n-particle and 2n-hole configuration mixing for $n = 0$ up to a finite $n$ is also exactly solvable by using the identities and procedures shown in Sec. 2. This is because the eigenstates of the model can always be expressed in terms of binomials of $s$- and $d$-boson pair operators, although the equations involved become more complicated. A similar extension to the IBM-II case is likewise straightforward. Moreover, a chain of isotopes or isotones in the vibrational to $\gamma$-soft transitional region may be analyzed using the model to reveal their shape phase coexistence and evolution, for example, as the analysis for Cd isotopes shown in [22–24], which will be considered in our future study.

One of the authors (F. Pan) is grateful to Professor P. Van Isacker for stimulating discussions on the subject and his suggestion on conducting this work.
