#### Abstract

In this paper，we calculate the branching ratios and the direct $C P$－violating asymmetries for decays $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{0}(980) \pi^{0}, \mathrm{a}_{0}^{+}(980) \pi^{-}, \mathrm{a}_{0}^{-}(980) \pi^{+}$and $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{0}(980) \pi^{-}, \mathrm{a}_{0}^{-}(980) \pi^{0}$ by employing the perturbative QCD （ pQCD ）factorization approach at the leading order．We found that（a）the pQCD predictions for the branching ratios are around $(0.4-2.8) \times 10^{-6}$ ，consistent with currently available experimental upper limits；（b）the $C P$ asymmetries of $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{0}(980) \pi^{0}$ and $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{-}(980) \pi^{0}$ decays can be large，about（70－80）\％for $\alpha=100^{\circ}$ ．

Key words B meson decay，the pQCD factorization approach，branching ratio，$C P$ asymmetry

## 1 Introduction

The study about scalar meson is an interesting topic for both theory and experiment．In order to uncover their mysterious structure，intensive studies have been done for the B meson decays involving a scalar meson as one of the two final state mesons． Such decays have been studied by employing vari－ ous factorization approaches，such as the QCD factor－ ization（QCDF）approach［1］，the perturbative QCD （ pQCD ）approach［2－5］，and by using the QCD sum rule［6］．

On the experimental side，the scalar meson $f_{0}(980)$ was observed in the decay mode $B \rightarrow f_{0}(980) K$ by Belle［7］，and confirmed by BaBar［8］later．Then many channels involving a scalar in the final state have been measured by Belle［9］and BaBar［10］．The decays $\mathrm{B} \rightarrow \mathrm{a}_{0}(980) \pi$ have also been studied by Bar－ Bar［11］，In Ref．［12］the authors argued that if the branching ratio of $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{-}(980) \pi^{0}$ decay can be mea－ sured accurately，one can separate the four－and two－ quark assignments，because the predictions of these two assignments have a difference of one order of mag－ nitude．So in the past three years，BarBar has given this channel two measurements［13］and got two al－ most identical upper limits．For our considered de－ cays，only the experimental upper limits are available
now for some of them［14］：

$$
\begin{align*}
& \operatorname{Br}\left(\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{+}(980) \pi^{-}\right)<3.1 \times 10^{-6} \\
& \operatorname{Br}\left(\mathrm{~B}^{-} \rightarrow \mathrm{a}_{0}^{-}(980) \pi^{0}\right)<1.4 \times 10^{-6} \\
& \operatorname{Br}\left(\mathrm{~B}^{-} \rightarrow \mathrm{a}_{0}^{0}(980) \pi^{-}\right)<5.8 \times 10^{-6} \tag{1}
\end{align*}
$$

In this paper，we will study the branching ratios and $C P$ asymmetries of $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{0}(980) \pi^{0}, \mathrm{a}_{0}^{ \pm}(980) \pi^{\mp}$ and $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{-}(980) \pi^{0}, \mathrm{a}_{0}^{0}(980) \pi^{-}$by employing the pQCD factorization approach．In the following，we use $\mathrm{a}_{0}$ to denote $\mathrm{a}_{0}(980)$ in some places for conve－ nience．The paper is organized as follows．In Sec．2， the status of the study on the physical properties of $\mathrm{a}_{0}$ ，the relevant decay constants and light－cone dis－ tribution amplitudes are discussed．In Sec．3，we then study these decay channels using the pQCD ap－ proach．The numerical results and the discussions are given in Section 4．The conclusions are presented in the final section．

## 2 Physical properties of the final par－ ticles

Many scalar mesons below 2 GeV have been found in experiments．We can not accommodate these scalar mesons into one nonet，but need at least two nonets below and above 1 GeV ［15］．Among them， the scalar mesons below 1 GeV ，including $\mathrm{f}_{0}(600)(\sigma)$ ，

[^0]$\mathrm{f}_{0}(980), \mathrm{K}_{0}^{*}(800)(\kappa)$ and $\mathrm{a}_{0}(980)$, are usually viewed to form a $S U(3)$ nonet; while scalar mseons above 1 GeV , including $\mathrm{f}_{0}(1370), \mathrm{f}_{0}(1500) / \mathrm{f}_{0}(1700)$, $\mathrm{K}^{*}(1430)$ and $\mathrm{a}_{0}(1450)$ form another $S U(3)$ nonet. There are several different scenarios to describe these mesons in the quark model [16-19]. For example, the $\mathrm{a}_{0}(980)$ meson has been suggested as a $\bar{q} q$ lowest lying state [16] (called scenario I ) or a four-quark bound state [17] (called scenario II ). In Scenario I , the former $S U(3)$ nonet mesons are treated as the $\bar{q} q$ ground stats, while the latter nonet ones are the first excited states; in Scenario II, the former nonet mesons are viewed as four-quark bound states, while the latter nonet ones are $\bar{q} q$ ground states. Some people also consider that it is not made of one simple component but might have a more complex nature such as having a $\mathrm{K} \overline{\mathrm{K}}$ component $[18,19]$, even the superpositions of the two- and four- quark states. In order to make quantitative predictions, we identify $\mathrm{a}_{0}(980)$ as the two-quark state in the calculation.

In the 2-quark model, the decay constants for scalar meson $\mathrm{a}_{0}$ are defined by:

$$
\left\langle\mathrm{a}_{0}(p)\right| \overline{\mathrm{q}}_{2} \gamma_{\mu} \mathrm{q}_{1}|0\rangle=f_{\mathrm{a}_{0}} p_{\mu},\left\langle\mathrm{a}_{0}(p)\right| \overline{\mathrm{q}}_{2} \mathrm{q}_{1}|0\rangle=m_{\mathrm{a}_{0}} \overline{\mathrm{a}}_{\mathrm{a}_{0}} .(2)
$$

Since the neutral scalar meson $\mathrm{a}_{0}$ cannot be produced via the vector current (restricted by the charge conjugation invariance or the $G$ parity conservation), the vector decay constant $f_{\mathrm{a}_{0}}=0$. As to the charged scalar mesons $\mathrm{a}_{0}^{-}$, from the equation of motion:

$$
\begin{equation*}
\mu_{\mathrm{a}_{0}^{-}} f_{\mathrm{a}_{0}^{-}}=\bar{f}_{\mathrm{a}_{0}^{-}}, \quad \text { with } \quad \mu_{\mathrm{a}_{0}^{-}}=\frac{m_{\mathrm{a}_{0}^{-}}}{m_{\mathrm{d}}(\mu)-m_{\mathrm{u}}(\mu)} \tag{3}
\end{equation*}
$$

its vector decay constant is proportional to the mass difference between the constituent $u$ and d quarks. It is easy to see the vector decay constant is very small, and will equal zero in the $S U(3)$ limit. So we only need to consider the scalar decay constant $\bar{f}_{\mathrm{a}_{0}}$, which is scale dependent. Fixing the scale at 1 GeV , the value is $\bar{f}_{\mathrm{a}_{0}}=(365 \pm 20) \mathrm{MeV}$, which is calculated in QCD sum rules [1].

The light-cone distribution amplitudes (LCDAs) for the scalar meson $\mathrm{a}_{0}$ can be written as:

$$
\begin{align*}
& \left\langle\mathrm{a}_{0}(p)\right| \overline{\mathrm{q}}_{1}(z)_{1} \mathrm{q}_{2}(0)_{\mathrm{j}}|0\rangle=\frac{1}{\sqrt{6}} \int_{0}^{1} \mathrm{~d} x \mathrm{e}^{\mathrm{i} x p \cdot z}\left\{\not p \Phi_{\mathrm{a}_{0}}(x)+\right. \\
& \left.m_{\mathrm{a}_{0}} \Phi_{\mathrm{a}_{0}}^{\mathrm{S}}(x)+m_{\mathrm{a}_{0}}\left(\not h_{+} \not h_{-}-1\right) \Phi_{\mathrm{a}_{0}}^{\mathrm{T}}(x)\right\}_{\mathrm{j} 1} \tag{4}
\end{align*}
$$

where $n_{+}$and $n_{-}$are the light-like vectors: $n_{+}=$ $\left(1,0,0_{\mathrm{T}}\right), n_{-}=\left(0,1,0_{\mathrm{T}}\right)$, and $n_{+}$is parallel with the moving direction of the scalar meson $a_{0}$. The normal-
ization can be related to the decay constants:

$$
\begin{align*}
& \int_{0}^{1} \mathrm{~d} x \Phi_{\mathrm{a}_{0}}(x)=\int_{0}^{1} \mathrm{~d} x \Phi_{\mathrm{a}_{0}}^{\mathrm{T}}(x)=0 \\
& \int_{0}^{1} \mathrm{~d} x \Phi_{\mathrm{a}_{0}}^{\mathrm{S}}(x)=\frac{\bar{f}_{\mathrm{a}_{0}}}{2 \sqrt{2 N_{\mathrm{c}}}} \tag{5}
\end{align*}
$$

The twist-2 LCDA can be expanded in the Gegenbauer polynomials:

$$
\begin{align*}
\Phi_{\mathrm{a}_{0}}(x, \mu)= & \frac{1}{2 \sqrt{2 N_{\mathrm{c}}}} \bar{f}_{\mathrm{a}_{0}}(\mu) 6 x(1-x) \times \\
& \sum_{m=1}^{\infty} B_{m}(\mu) C_{m}^{3 / 2}(2 x-1) \tag{6}
\end{align*}
$$

the values for Gegenbauer moments $B_{1}, B_{3}$ have been calculated in Ref. [1] as:

$$
\begin{equation*}
B_{1}=-0.93 \pm 0.10, \quad B_{3}=0.14 \pm 0.08 \tag{7}
\end{equation*}
$$

These values are taken at $\mu=1 \mathrm{GeV}$ and the even Gegenbauer moments vanish.

As for the twist-3 distribution amplitudes $\Phi_{\mathrm{a}_{0}}^{\mathrm{S}}$ and $\Phi_{\mathrm{a}_{0}}^{\mathrm{T}}$, they have not been studied in the literature, so we adopt the asymptotic form [5]:

$$
\begin{align*}
\Phi_{\mathrm{a}_{0}}^{\mathrm{S}} & =\frac{1}{2 \sqrt{2 N_{\mathrm{c}}}} \bar{f}_{\mathrm{a}_{0}} \\
\Phi_{\mathrm{a}_{0}}^{\mathrm{T}} & =\frac{1}{2 \sqrt{2 N_{\mathrm{c}}}} \bar{f}_{\mathrm{a}_{0}}(1-2 x) . \tag{8}
\end{align*}
$$

## 3 The perturbative QCD calculation

In the pQCD approach, the decay amplitude of $\mathrm{B} \rightarrow \mathrm{a}_{0} \pi$ decays can be conceptually written as the convolution,

$$
\begin{align*}
& \mathcal{A}\left(\mathrm{B} \rightarrow \pi \mathrm{a}_{0}\right) \sim \int \mathrm{d}^{4} k_{1} \mathrm{~d}^{4} k_{2} \mathrm{~d}^{4} k_{3} \times \\
& \operatorname{Tr}\left[C(t) \Phi_{B}\left(k_{1}\right) \Phi_{\pi}\left(k_{2}\right) \Phi_{\mathrm{a}_{0}}\left(k_{3}\right) H\left(k_{1}, k_{2}, k_{3}, t\right)\right] \tag{9}
\end{align*}
$$

where $k_{i}$ 's are the momenta of light quarks included in each mesons, and $\operatorname{Tr}$ denotes the trace over Dirac and color indices. $C(t)$ is the Wilson coefficient, $H\left(k_{1}, k_{2}, k_{3}, t\right)$ is the hard kernel which describes the four quark operator and the spectator quark connected by a hard gluon, and can be perturbatively calculated. The functions $\Phi_{\mathrm{B}}, \Phi_{\pi}$ and $\Phi_{\mathrm{a}_{0}}$ are the wave functions of the $\mathrm{B}, \pi$ and $\mathrm{a}_{0}$ meson, respectively.

Since the b quark is rather heavy we consider the B meson at rest for simplicity. It is convenient to use light-cone coordinate $\left(p^{+}, p^{-}, \boldsymbol{p}_{\mathrm{T}}\right)$ to describe the meson's momenta: $p^{ \pm}=\left(p^{0} \pm p^{3}\right) / \sqrt{2}$, and $\boldsymbol{p}_{\mathrm{T}}=\left(p^{1}, p^{2}\right)$. Using these coordinates the B meson and the two final
state meson momenta can be written as

$$
\begin{align*}
P_{\mathrm{B}} & =\frac{M_{\mathrm{B}}}{\sqrt{2}}\left(1,1, \mathbf{0}_{\mathrm{T}}\right), \\
P_{2} & =\frac{M_{\mathrm{B}}}{\sqrt{2}}\left(1,0, \mathbf{0}_{\mathrm{T}}\right)  \tag{10}\\
P_{3} & =\frac{M_{\mathrm{B}}}{\sqrt{2}}\left(0,1, \mathbf{0}_{\mathrm{T}}\right),
\end{align*}
$$

respectively. The light meson masses $m_{\pi}$ and $m\left(\mathrm{a}_{0}\right)$ have been neglected. Putting the anti- quark momenta in $\mathrm{B}, \pi$ and $\mathrm{a}_{0}$ mesons as $k_{1}, k_{2}$, and $k_{3}$, respectively, we can choose

$$
\begin{align*}
& k_{1}=\left(x_{1} P_{1}^{+}, 0, \boldsymbol{k}_{1 \mathrm{~T}}\right), \\
& k_{2}=\left(x_{2} P_{2}^{+}, 0, \boldsymbol{k}_{2 \mathrm{~T}}\right),  \tag{11}\\
& k_{3}=\left(0, x_{3} P_{3}^{-}, \boldsymbol{k}_{3 \mathrm{~T}}\right) .
\end{align*}
$$

For these considered decay channels, the integration over $k_{1}^{-}, k_{2}^{-}$, and $k_{3}^{+}$in Eq. (9) will lead to

$$
\begin{align*}
\mathcal{A}\left(\mathrm{B} \rightarrow \pi \mathrm{a}_{0}\right) \sim & \int \mathrm{d} x_{1} \mathrm{~d} x_{2} \mathrm{~d} x_{3} b_{1} \mathrm{~d} b_{1} b_{2} \mathrm{~d} b_{2} b_{3} \mathrm{~d} b_{3} \times \\
& \operatorname{Tr}\left[C(t) \Phi_{\mathrm{B}}\left(x_{1}, b_{1}\right) \Phi_{\pi}\left(x_{2}, b_{2}\right) \times\right. \\
& \left.\Phi_{\mathrm{a}_{0}}\left(x_{3}, b_{3}\right) H\left(x_{i}, b_{i}, t\right) S_{t}\left(x_{i}\right) \mathrm{e}^{-S(t)}\right] \tag{12}
\end{align*}
$$

where $b_{i}$ is the conjugate space coordinate of $k_{i \mathrm{~T}}$, and $t$ is the largest energy scale in function $H\left(x_{i}, b_{i}, t\right)$. In order to smear the end-point singularity on $x_{i}$, the jet function $S_{\mathrm{t}}(x)$ [20], which comes from the resummation of the double logarithms $\ln ^{2} x_{i}$, is used

$$
\begin{equation*}
S_{\mathrm{t}}(x)=\frac{2^{1+2 c} \Gamma(3 / 2+c)}{\sqrt{\pi} \Gamma(1+c)}[x(1-x)]^{c} \tag{13}
\end{equation*}
$$

where the parameter $c=0.4$. The last term $\mathrm{e}^{-S(t)}$ in Eq. (12) is the Sudakov form factor which suppresses the soft dynamics effectively [21].

For the considered decays, the related weak effective Hamiltonian $\mathcal{H}_{\text {eff }}$ can be written as [22]

$$
\begin{align*}
\mathcal{H}_{\mathrm{eff}}= & \frac{G_{\mathrm{F}}}{\sqrt{2}} \sum_{\mathrm{q}=\mathrm{u}, \mathrm{c}} V_{\mathrm{qb}} V_{\mathrm{qd}}^{*}\left[\left(C_{1}(\mu) O_{1}^{q}(\mu)+C_{2}(\mu) O_{2}^{q}(\mu)\right) \times\right. \\
& \left.\sum_{i=3}^{10} C_{i}(\mu) O_{i}(\mu)\right] \tag{14}
\end{align*}
$$

with $G_{\mathrm{F}}=1.16639 \times 10^{-5} \mathrm{GeV}^{-2}$ is the Fermi constant, $V_{i j}$ are the CKM matrix elements, $C_{i}(\mu)$ and $O_{i}(\mu)$ are the Wilson coefficients and the corresponding 4-quark operators.

In the following, we take the $\overline{\mathrm{B}}^{0} \rightarrow \pi^{0} \mathrm{a}_{0}^{0}$ decay channel as an example. There are 8 type diagrams contributing to this decay, as illustrated in Fig. 1. For
the factorizable emission diagrams (a) and (b), operators $O_{1-4,9,10}$ are $(V-A)(V-A)$ currents, and the operators $O_{5-8}$ have a structure of $(V-A)(V+A)$, the sum of the amplitudes are written as $F_{\mathrm{e} \pi}$ and $F_{\mathrm{e} \pi}^{P 1}$. In some other cases, we need to do Fierz transformation for the $(V-A)(V+A)$ operators and get $(S-P)(S+P)$ ones which hold the right flavor and color structure for factorization to work. The contribution from the operator $(S-P)(S+P)$ type is written as $F_{\mathrm{e} \pi}^{P 2}$. Similarly, for the factorizable annihilation diagrams $(\mathrm{g})$ and (h), the contributions from $(V-A)(V-A),(V-A)(V+A),(S-P)(S+P)$ currents are $F_{\mathrm{a} \pi}, F_{\mathrm{a} \pi}^{P 1}$ and $F_{\mathrm{a} \pi}^{P 2}$. For the nonfactorizable spectator diagrams ( $c, d$ ) and the nonfactorizable annihilation diagrams (e, f), these three kinds of contributions can be written as $M_{\mathrm{e} \pi}, M_{\mathrm{e} \pi}^{P 1}, M_{\mathrm{e} \pi}^{P 2}$ and $M_{\mathrm{a} \pi}, M_{\mathrm{a} \pi}^{P 1}, M_{\mathrm{a} \pi}^{P 2}$, respectively. Since these amplitudes are similar to those of $\mathrm{B} \rightarrow \mathrm{f}_{0}(980) \mathrm{K}\left(\pi, \eta^{(\prime)}\right)[3,4]$ or $\mathrm{B} \rightarrow \mathrm{a}_{0}(980) \mathrm{K}$ [5], we just need to replace some corresponding wave functions and parameters.

Combining the contributions from different diagrams, the total decay amplitudes for those considered decays can be written as:

Fig. 1. Typical Feynman diagrams contributing to the decay $\overline{\mathrm{B}}^{0} \rightarrow \pi^{0} a_{0}^{0}$.

$$
\begin{align*}
& 2 \mathcal{M}\left(\overline{\mathrm{~B}}^{0} \rightarrow \mathrm{a}_{0}^{0} \pi^{0}\right)=\xi_{\mathrm{u}}\left[\left(-M_{\mathrm{e} \pi}+M_{\mathrm{a} \pi}+M_{\text {ea }}+M_{\mathrm{aa}_{0}}\right) C_{2}+\left(F_{\mathrm{a} \pi}+F_{\text {ea } 0}+F_{\mathrm{aza}_{0}}\right) a_{2}\right]- \\
& \xi_{\mathrm{t}}\left\{\left(M_{\mathrm{er}}^{P 1}+M_{\mathrm{a} \pi}^{P 1}+M_{\mathrm{eao}}^{P 1}+M_{\mathrm{aao}_{0}}^{P 1}\right)\left(C_{5}-\frac{1}{2} C_{7}\right)+\right. \\
& \left(M_{\text {ел }}+M_{\mathrm{a} \pi}+M_{\text {eä }}+M_{\text {ааа }}\right)\left(C_{3}+2 C_{4}-\frac{1}{2} C_{9}+\frac{1}{2} C_{10}\right)+ \\

& M_{\text {ea } 0}\left(C_{3}+C_{9}\right)+M_{\text {aad }_{0}}^{P 2}\left(C_{6}-\frac{1}{2} C_{8}\right)+M_{\text {ã }}^{P 2}\left(C_{6}+C_{8}\right)+ \\
& F_{\text {aao }}\left(a_{3}+a_{4}-a_{5}+\frac{1}{2} a_{7}-\frac{1}{2} a_{9}-\frac{1}{2} a_{10}\right)+F_{\text {ea0 }}\left(a_{4}+a_{10}\right)+ \\
& \left.F_{\mathrm{a} \pi}\left(a_{3}+a_{9}-a_{5}-a_{7}\right)+F_{\text {eao }}^{P 2}\left(a_{6}+a_{8}\right)+F_{\text {ão }}^{P 2}\left(a_{6}-\frac{1}{2} a_{8}\right)\right\}, \tag{17}
\end{align*}
$$

$$
\begin{align*}
& \xi_{\mathrm{t}}\left\{-M_{\mathrm{e} \pi}^{P 1}\left(C_{5}-\frac{1}{2} C_{7}\right)+\left(-M_{\mathrm{a} \pi}^{P 1}+M_{\text {eao }}^{P 1}+M_{\mathrm{aa} 0}^{P 1}\right)\left(C_{5}+C_{7}\right)+\right. \\
& M_{\text {er }}\left(-C_{3}+\frac{1}{2} C_{9}+\frac{3}{2} C_{10}\right)+\left(-M_{\text {ã }}+M_{\text {eap }}+M_{\text {aap }_{0}}\right)\left(C_{3}+C_{9}\right)+ \\
& \frac{3}{2} C_{8} M_{\mathrm{e} \pi}^{P 2}+\left(-F_{\text {ã }}+F_{\text {ea }}+F_{\text {aа }_{0}}\right)\left(a_{4}+a_{10}\right)-F_{\text {ẽ }}^{P 2}\left(a_{6}-\frac{1}{2} a_{8}\right)+ \\
& \left.\left(-F_{\mathrm{a} \pi}^{P 2}+F_{\text {ea }}^{P 2}+F_{\text {aа }}^{P 2}\right)\left(a_{6}+a_{8}\right)\right\}, \tag{18}
\end{align*}
$$

$$
\begin{align*}
\sqrt{2} \mathcal{M}\left(\mathrm{~B}^{-} \rightarrow \mathrm{a}_{0}^{-} \pi^{0}\right)= & \xi_{\mathrm{u}}\left[M_{\mathrm{ea}_{0}} C_{2}+\left(-M_{\mathrm{aa}_{0}}+M_{\mathrm{e} \pi}+M_{\mathrm{a} \pi}\right) C_{1}+F_{\mathrm{ea} 0} a_{2}+\left(-F_{\mathrm{aa}_{0}}+F_{\mathrm{e} \pi}+F_{\mathrm{a} \pi}\right) a_{1}\right]- \\
& \xi_{\mathrm{t}}\left\{-M_{\mathrm{ea}_{0}}^{P 1}\left(C_{5}-\frac{1}{2} C_{7}\right)+\left(-M_{\mathrm{aa}_{0}}^{P 1}+M_{\mathrm{e} \pi}^{P 1}+M_{\mathrm{a} \pi}^{P 1}\right)\left(C_{5}+C_{7}\right)+\right. \\
& M_{\mathrm{ea}_{0}}\left(-C_{3}+\frac{1}{2} C_{9}+\frac{3}{2} C_{10}\right)+\left(-M_{\mathrm{aa}_{0}}+M_{\mathrm{e} \pi}+M_{\mathrm{a} \pi}\right)\left(C_{3}+C_{9}\right)+ \\
& \frac{3}{2} C_{8} M_{\mathrm{ea}_{0}}^{P 2}+\left(-F_{\mathrm{aa}_{0}}+F_{\mathrm{e} \pi}+F_{\mathrm{a} \pi}\right)\left(a_{4}+a_{10}\right)-F_{\mathrm{ea} 0}^{P 2}\left(a_{6}-\frac{1}{2} a_{8}\right)+ \\
& \left.F_{\mathrm{ea}_{0}}\left(-a_{4}-\frac{3}{2} a_{7}+\frac{3}{2} a_{9}+\frac{1}{2} a_{10}\right)+\left(-F_{\mathrm{aa}_{0}}^{P 2}+F_{\mathrm{ea} 0}^{P 2}+F_{\mathrm{a} \pi}^{P 2}\right)\left(a_{6}+a_{8}\right)\right\}, \tag{19}
\end{align*}
$$

where $\xi_{\mathrm{u}}=V_{\mathrm{ub}} V_{\mathrm{ud}}^{*}, \xi_{\mathrm{t}}=V_{\mathrm{tb}} V_{\mathrm{td}}^{*}$, and $a_{i}$ are the combinations of the Wilson coefficients defined as usual in Ref. [23].

## 4 Numerical results and discussions

In the numerical calculation, we will use the input parameters as listed in Table 1.

In the B-rest frame, the decay rates of $\mathrm{B} \rightarrow$ $\mathrm{a}_{0}(980) \pi$ can be written as:

$$
\begin{equation*}
\Gamma=\frac{G_{\mathrm{F}}^{2}}{32 \pi m_{\mathrm{B}}}|\mathcal{M}|^{2}\left(1-r_{\mathrm{a}_{0}}^{2}\right), \tag{20}
\end{equation*}
$$

where $r_{\mathrm{a}_{0}}=m_{\mathrm{a}_{0}} / m_{\mathrm{B}}$ and $\mathcal{M}$ is the total decay amplitude of $\mathrm{B} \rightarrow \mathrm{a}_{0}(980) \pi$ as given in the last section.

Using the wave functions as specified in previous section and the input parameters listed in Table 1, it is straightforward to calculate the $C P$-averaged branching ratios for the considered decays, which are listed in Table 2. In this table, we have included the theoretical errors arising from the uncertainties in the
scalar meson decay constant $\bar{f}_{\mathrm{a}_{0}}$ and the Gengebauaer moments $B_{1}$ and $B_{3}$ for twist-2 LCDAs of $\mathrm{a}_{0}(980)$. In Fig. 2, we plot the branching ratios of $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{0} \pi^{0}$, $\mathrm{a}_{0}^{-} \pi^{+}, \mathrm{a}_{0}^{+} \pi^{-}$and $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{0} \pi^{-}, \mathrm{a}_{0}^{-} \pi^{0}$ as a function of the CKM angle $\alpha$ :

$$
\alpha=\arg \left[-\frac{V_{\mathrm{td}} V_{\mathrm{tb}}^{*}}{V_{\mathrm{ud}} V_{\mathrm{ub}}^{*}}\right]
$$

From the numerical results, one can see that:

1) Because of the small $u \bar{u}$ and $d \bar{d}$ component in the $f_{0}(980)$, the branching ratio of $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{0} \pi^{0}$ is about one order larger than that of $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{f}_{0}(980) \pi^{0}$ $\left(\operatorname{Br}\left(\overline{\mathrm{B}}^{0} \rightarrow \mathrm{f}_{0}(980) \pi^{0}\right) \sim 4.7 \times 10^{-8}[4]\right)$, but much smaller than the branching ratio $\operatorname{Br}\left(\overline{\mathrm{B}}^{0} \rightarrow \pi^{0} \pi^{0}\right)=$ $(1.62 \pm 0.31) \times 10^{-6}$.
2) In order to compare with the experimental measurements [11], we also define the branching ratio $\operatorname{Br}\left(\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{-} \pi^{+}+\mathrm{a}_{0}^{+} \pi^{-}\right)$as the direct sum of $\operatorname{Br}\left(\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{-} \pi^{+}\right)$and $\operatorname{Br}\left(\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{+} \pi^{-}\right)$, and show it in Table 2.

Table 1. Input parameters used in the numerical calculation.

| masses | $m_{\mathrm{a}_{0}}=0.9847 \mathrm{GeV}$, | $m_{0}^{\pi}=1.3 \mathrm{GeV}$, |
| :---: | :---: | :---: |

| $\mathrm{~B}^{-} \rightarrow \mathrm{a}_{0}^{0} \pi^{-}$ | $2.8_{-0.79-0.85-0.58}^{+0.00+0.00+0.00}$ | $<1.4$ | $<5.8$ |

Fig. 2. Branching ratios (in units of $10^{-6}$ ) of (a) $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{0} \pi^{0}$ (solid curve), $\mathrm{a}_{0}^{-} \pi^{+}$(dotted curve), $\mathrm{a}_{0}^{+} \pi^{-}$(dashed curve) and (b) $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{-} \pi^{0}$ (solid curve), $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{0} \pi^{-}$(dashed curve) decays as a function of the CKM angle $\alpha$.

Fig. 3. The direct $C P$ asymmetries (a) of the decays $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{0} \pi^{0}$ (solid curve), $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{-} \pi^{0}$ (dashed curve), $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{0} \pi^{-}$(dotted cureve) and the $C P$ asymmetry parameters (b) of the decay $\mathrm{B}^{0} / \overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{+} \pi^{-}+\mathrm{a}_{0}^{-} \pi^{+}$: $a_{\epsilon^{\prime}}$ (dash-dotted curve), $a_{\bar{\epsilon}^{\prime}}$ (dotted cureve), $a_{\epsilon+\epsilon^{\prime}}$ (dashed cureve) and $a_{\epsilon+\bar{\epsilon}^{\prime}}$ (solid curve) as functions of the CKM angle $\alpha$.
3) The pQCD predictions for branching ratios are all consistent with currently available experimental upper limits. The 2-quark model supposition of $\mathrm{a}_{0}(980)$ can not be ruled out by the current experimental data.

Now we turn to the evaluations of the $C P$ violating asymmetries of $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{-} \pi^{0}, \mathrm{a}_{0}^{0} \pi^{-}$and $\overline{\mathrm{B}} \rightarrow \mathrm{a}_{0}^{0} \pi^{0}, \mathrm{a}_{0}^{ \pm} \pi^{\mp}$ decays in the pQCD approach. For the charged decay channels, the direct $C P$ violating asymmetry can be defined as $\mathcal{A}_{C P}^{\text {dir }}=\left(|\overline{\mathcal{A}}|^{2}-\right.$ $\left.|\mathcal{A}|^{2}\right) /\left(|\mathcal{A}|^{2}+|\overline{\mathcal{A}}|^{2}\right)$. For the neutral decays $\overline{\mathrm{B}}^{0} \rightarrow$ $\mathrm{a}_{0}^{0} \pi^{0}$, there are both direct $C P$ asymmetry $\mathcal{A}_{C P}^{\text {dir }}$ and mixing-induced $C P$ asymmetry $\mathcal{A}_{C P}^{\text {mix }}$ :

$$
\begin{align*}
& \mathcal{A}_{C P}^{\mathrm{dir}}\left(\mathrm{~B}_{\mathrm{d}} \rightarrow \mathrm{f}\right)=\frac{|\lambda|^{2}-1}{1+|\lambda|^{2}}, \\
& \mathcal{A}_{C P}^{\mathrm{mix}}\left(\mathrm{~B}_{\mathrm{d}} \rightarrow \mathrm{f}\right)=\frac{2 \operatorname{Im} \lambda}{1+|\lambda|^{2}}, \tag{21}
\end{align*}
$$

where

$$
\lambda=\eta_{C P} \mathrm{e}^{-2 \mathrm{i} \beta} \frac{\mathcal{A}\left(\overline{\mathrm{~B}}_{\mathrm{d}} \rightarrow \mathrm{f}\right)}{\mathcal{A}\left(\mathrm{B}_{\mathrm{d}} \rightarrow \mathrm{f}\right)}
$$

with $\eta_{C P}= \pm 1$ the $C P$ eigenvalue of the final state f .
As to the decays $\overline{\mathrm{B}} \rightarrow \mathrm{a}_{0}^{ \pm} \pi^{\mp}$, since both $\mathrm{B}^{0}$ and $\overline{\mathrm{B}}^{0}$ can decay into the final state $\mathrm{a}_{0}^{+} \pi^{-}$and $\mathrm{a}_{0}^{-} \pi^{+}$, the four time-dependent decay widths for $\mathrm{B}^{0}(\mathrm{t}) \rightarrow \mathrm{a}_{0}^{+} \pi^{-}$, $\overline{\mathrm{B}}^{0}(\mathrm{t}) \rightarrow \mathrm{a}_{0}^{-} \pi^{+}, \mathrm{B}^{0}(\mathrm{t}) \rightarrow \mathrm{a}_{0}^{-} \pi^{+}$and $\overline{\mathrm{B}}^{0}(\mathrm{t}) \rightarrow \mathrm{a}_{0}^{+} \pi^{-}$can be expressed by four basic matrix elements:

$$
\begin{array}{ll}
g=\left\langle\mathrm{a}_{0}^{+} \pi^{-}\right| H_{\mathrm{eff}}\left|B^{0}\right\rangle, & h=\left\langle\mathrm{a}_{0}^{+} \pi^{-}\right| H_{\mathrm{eff}}\left|\overline{\mathrm{~B}}^{0}\right\rangle, \\
\bar{g}=\left\langle\mathrm{a}_{0}^{-} \pi^{+}\right| H_{\mathrm{eff}}\left|\overline{\mathrm{~B}}^{0}\right\rangle, \quad \bar{h}=\left\langle\mathrm{a}_{0}^{-} \pi^{+}\right| H_{\mathrm{eff}}\left|\mathrm{~B}^{0}\right\rangle . \tag{22}
\end{array}
$$

Following the notation of Refs. [22, 23], the four $C P$ violating parameters are given by the following formulae:

$$
\begin{align*}
& a_{\epsilon^{\prime}}=\frac{|g|^{2}-|h|^{2}}{|g|^{2}+|h|^{2}}, \quad a_{\epsilon+\epsilon^{\prime}}=\frac{-2 \operatorname{Im}\left(\frac{q}{p} \frac{h}{g}\right)}{1+|h / g|^{2}}, \\
& a_{\bar{\epsilon}^{\prime}}=\frac{|\bar{h}|^{2}-|\bar{g}|^{2}}{|\bar{h}|^{2}+|\bar{g}|^{2}}, \quad a_{\epsilon+\bar{\epsilon}^{\prime}}=\frac{-2 \operatorname{Im}\left(\frac{q}{p} \frac{\bar{g}}{\bar{h}}\right)}{1+|\bar{g} / \bar{h}|^{2}} \tag{23}
\end{align*}
$$

where $q / p=\mathrm{e}^{-2 \mathrm{i} \beta}$ with $|p|^{2}+|q|^{2}=1$ and $\beta$ is one of the three CKM angles.

From Fig. 3(b), one can find the central values of the $C P$-violation parameters:

$$
a_{\epsilon^{\prime}}=0.31, a_{\epsilon+\epsilon^{\prime}}=0.94, a_{\bar{\epsilon}^{\prime}}=0.93, a_{\epsilon+\bar{\epsilon}^{\prime}}=0.32, \text { (24) }
$$

for $\alpha=100^{\circ}$.
For $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{0} \pi^{0}, \mathrm{a}_{0}^{-} \pi^{0}$, and $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{0} \pi^{-}$decays, the $\alpha$-dependence of their direct $C P$ asymmetries is shown in Fig. 3(a). Although the branching ratio of $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{0} \pi^{-}$decay is the largest one among the considered channels, its direct $C P$ asymmetry is the smallest one, about $14 \%$ for a fixed $\alpha=100^{\circ}$. For $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{0}(980) \pi^{0}$ and $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{-}(980) \pi^{0}$ decays, their $C P$ asymmetries can be large, about (70-80)\% for $\alpha=100^{\circ}$, but the corresponding branching ratios are
small,around $(4-5) \times 10^{-7}$, and therefore it is difficult to measure them.

## 5 Conclusion

In this paper, we calculate the branching ratios and $C P$-violating asymmetries of $\overline{\mathrm{B}}^{0} \rightarrow \mathrm{a}_{0}^{0} \pi^{0}, \mathrm{a}_{0}^{+} \pi^{-}$, $\mathrm{a}_{0}^{-} \pi^{+}$, and $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{0} \pi^{-}, \mathrm{a}_{0}^{-} \pi^{0}$ decays in the pQCD factorization approach by identifying $\mathrm{a}_{0}(980)$ as the 2-quark content. Based on the analytical calculations and numerical results, we find that:

1) The pQCD predictions for the branching ratios are around $(0.4-2.8) \times 10^{-6}$, consistent with currently available experimental upper limits. The 2 quark model supposition of $\mathrm{a}_{0}(980)$ can not be ruled out by the current experimental data.
2) Although the $C P$ asymmetries of $\overline{\mathrm{B}}^{0} \rightarrow$ $\mathrm{a}_{0}^{0}(980) \pi^{0}$ and $\mathrm{B}^{-} \rightarrow \mathrm{a}_{0}^{-}(980) \pi^{0}$ decays can be large, about $(70-80) \%$, it is still difficult to measure them due to their small branching ratios.

Zhang Zhi-Qing would like to thank Cheng HaiYang and Wang Wei for their helpful discussions.
