Abstract: We investigate the direct CP violation in the decay $D^\pm \rightarrow \pi^\pm \pi^+ \pi^-$ incorporating the $a_0^0(980)-f_0(980)$ mixing mechanism. The integrated mixing intensities $\bar{\xi}_{fa}$ and $\bar{\xi}_{af}$ are calculated using meson masses and coupling constants extracted from various theoretical models and experimental data, yielding values of appreciable magnitude. We find that when the invariant mass of the $\pi^+ \pi^-$ pair lies near the $f_0(980)$ resonance, this isospin-breaking mechanism can enhance the CP asymmetry. The enhancement is particularly pronounced when the $f_0(980)$ carries a significant $n\bar{n}$ quark component and the $f_0(980)$ and $\sigma(600)$ mixing angle is approximately 26° . After accounting for non-factorizable effects, we find these corrections tend to partially cancel the leading-order contributions, resulting in a suppression of the CP violations relative to the naive factorization predictions. It is emphasized that the $a_0^0(980)-f_0(980)$ mixing mechanism should be taken into account in both theoretical and experimental studies of CP violation in B or D meson decays.

Keywords: CP violation, D meson decay, isospin breaking

I. INTRODUCTION

Charge-Parity (CP) violation is a fundamental phenomenon in particle physics with direct implications for the observed matter-antimatter asymmetry of the Universe. First established in neutral kaon decays in 1964 [1], it remains a central subject of investigation within and beyond the Standard Model (SM). In the SM, CP violation originates from the irreducible complex phase of the Cabibbo-Kobayashi-Maskawa (CKM) matrix [2, 3], which governs quark-flavor mixing via the weak interaction.

In recent years, the LHCb collaboration has observed larger localized CP asymmetries in the Dalitz plot of the B three-body decays, notably in $B^\pm \rightarrow \pi^\pm \pi^+ \pi^-$ and $B^\pm \rightarrow K^\pm \pi^+ \pi^-$ [4]. These asymmetries can be attributed to interference between decay amplitudes from nearby res-

onances of different spin [5]. Meanwhile, isospin-breaking effects, such as $\rho-\omega$ mixing and $a_0^0(980)-f_0(980)$ mixing [6–10], also constitute important mechanisms for exploring CP violation. CP violation effects in D mesons are small, and the SM provides clear predictions for them. By precisely measuring CP violation in D mesons, we can test the accuracy of the SM, explore new physics, and gain a deeper understanding of the non-perturbative effects of strong interactions. The LHCb collaboration measured CP violation in the three-body decay $D^\pm \rightarrow \pi^\pm \pi^+ \pi^-$ [11]; no localized or overall CP asymmetries were found with high-statistics data. The BESIII collaboration also analyzed the amplitude of $D^+ \rightarrow \pi^+ \pi^0 \pi^0$ and measured CP asymmetries; the results show that no evidence for CP violation is observed [12]. As demonstrated in the aforementioned three-body decay channels of B mesons, localized CP asymmetries in phase space can be

enhanced by the interference between different intermediate resonances, and the same mechanism should also apply to D meson decays. Interference between different resonances, such as $\rho^0(770)$ and $f_0(500)$, has already been studied in three-body decays of D mesons [13], while the scalar type isospin breaking effect has not yet been investigated. Drawing inspiration from these, we will investigate the effects of the $a_0^0(980)$ - $f_0(980)$ mixing mechanism on D meson decays. The theoretical proposal of the $a_0^0(980)$ - $f_0(980)$ mixing effect can be traced to the late 1970s [14]. This isospin breaking effect results in an 8 MeV mass difference between the charged and neutral kaon thresholds when $a_0^0(980)$ and $f_0(980)$ decay into $K\bar{K}$. Over the years, the $a_0^0(980)$ - $f_0(980)$ mixing has been thoroughly investigated across various processes and from multiple perspectives [15–35]. The first experimental observation of this effect was made by the BESIII collaboration in the decays $J/\psi \rightarrow \phi f_0(980) \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0$ and $\chi_{c1} \rightarrow a_0^0(980) \pi^0 \rightarrow f_0(980) \pi^0 \rightarrow \pi^+ \pi^- \pi^0$ [36]. Similarly to B decay, we expect that $a_0^0(980)$ - $f_0(980)$ mixing could lead to magnified CP violation in the $D^\pm \rightarrow \pi^\pm \pi^+ \pi^-$ decay.

A study of the direct CP violation in the decay $D^\pm \rightarrow \pi^\pm \pi^+ \pi^-$ with $a_0^0(980)$ - $f_0(980)$ mixing is presented within the framework of the naive factorization approach. The organization of this paper is as follows. A brief overview of the $a_0^0(980)$ - $f_0(980)$ mixing mechanism is given in Sec. II. The formalism for the decay amplitudes and the CP violation calculation is developed in Sec. III. Numerical results are presented in Sec. IV, and a summary with discussion is provided in Sec. V. The theoretical input parameters used in this work are summarized in Appendix A.

II. $a_0^0(980)$ - $f_0(980)$ MIXING MECHANISM

A. $a_0^0(980)$ - $f_0(980)$ mixing amplitude

When the $a_0^0(980)$ - $f_0(980)$ mixing is active, the full propagator matrix is obtained by summing all chain transitions $a_0^0(980) \rightarrow f_0(980) \rightarrow \dots \rightarrow a_0^0(980)$ and $f_0(980) \rightarrow a_0^0(980) \rightarrow \dots \rightarrow f_0(980)$, respectively. The result is [34]:

$$\begin{pmatrix} P_{a_0}(s) & P_{a_0 f_0}(s) \\ P_{f_0 a_0}(s) & P_{f_0}(s) \end{pmatrix} = \frac{1}{D_{f_0}(s)D_{a_0}(s) - |D_{a_0 f_0}(s)|^2} \begin{pmatrix} D_{a_0}(s) & D_{a_0 f_0}(s) \\ D_{a_0 f_0}(s) & D_{f_0}(s) \end{pmatrix}, \quad (1)$$

where $P_{a_0}(s)$ and $P_{f_0}(s)$ represent the propagators of $a_0^0(980)$ and $f_0(980)$, respectively. The terms $P_{a_0 f_0}(s)$, $P_{f_0 a_0}(s)$, and $D_{a_0 f_0}(s)$ emerge as a consequence of the $a_0^0(980)$ - $f_0(980)$ mixing effect. The individual propagators take the form:

$$P_{a_0/f_0}(s) = \frac{D_{f_0/a_0}(s)}{D_{a_0/f_0}(s)D_{f_0/a_0}(s) - D_{a_0 f_0}(s)^2}. \quad (2)$$

Meanwhile, $D_{a_0}(s)$ and $D_{f_0}(s)$ denote the denominators of the propagators for $a_0(980)$ and $f_0(980)$ in the absence of the $a_0^0(980)$ - $f_0(980)$ mixing effect. These denominators can be expressed using the Flatté parametrization as follows:

$$\begin{aligned} D_{a_0}(s) &= m_{a_0}^2 - s - i\sqrt{s}[\Gamma_{\eta\pi}^{a_0}(s) + \Gamma_{K\bar{K}}^{a_0}(s)], \\ D_{f_0}(s) &= m_{f_0}^2 - s - i\sqrt{s}[\Gamma_{\pi\pi}^{f_0}(s) + \Gamma_{K\bar{K}}^{f_0}(s)], \end{aligned} \quad (3)$$

where m_{a_0} and m_{f_0} are the masses of the $a_0(980)$ and $f_0(980)$ mesons, with the decay width Γ_{bc}^a being presented as:

$$\begin{aligned} \Gamma_{bc}^a(s) &= \frac{g_{abc}^2}{16\pi\sqrt{s}}\rho_{bc}(s) \quad \text{with} \\ \rho_{bc}(s) &= \sqrt{\left[1 - \frac{(m_b - m_c)^2}{s}\right]\left[1 + \frac{(m_b - m_c)^2}{s}\right]}. \end{aligned} \quad (4)$$

It has been demonstrated that the contribution arising from the amplitude of $a_0^0(980)$ - $f_0(980)$ mixing is convergent [14, 37, 38]. When only the contributions from $K\bar{K}$ loop diagrams are taken into account, the amplitude can be expressed as an expansion within the $K\bar{K}$ phase space [37, 38]

$$\begin{aligned} D_{a_0 f_0}(s)_{K\bar{K}} &= \frac{g_{a_0 K^+ K^-} g_{f_0 K^+ K^-}}{16\pi} \left\{ i \left[\rho_{K^+ K^-}(s) - \rho_{K^0 \bar{K}^0}(s) \right] \right. \\ &\quad \left. - \mathcal{O}(\rho_{K^+ K^-}^2(s) - \rho_{K^0 \bar{K}^0}^2(s)) \right\}, \end{aligned} \quad (5)$$

where $g_{a_0 K^+ K^-}$ and $g_{f_0 K^+ K^-}$ are the effective coupling constants. Since the mixing mainly comes from the $K\bar{K}$ loops, we can adopt $D_{a_0 f_0}(s) \approx D_{a_0 f_0}(s)_{K\bar{K}}$.

B. $a_0^0(980)$ - $f_0(980)$ mixing intensity

There exist two types of reactions that can be utilized to investigate the $a_0^0(980)$ - $f_0(980)$ mixing: $X \rightarrow Y f_0(980) \rightarrow Y a_0^0(980) \rightarrow Y \pi^0 \eta$ and $X \rightarrow Y a_0^0(980) \rightarrow Y f_0(980) \rightarrow Y \pi \pi$. These two processes correspond to two different types of mixing, namely $f_0(980) \rightarrow a_0^0(980)$ and $a_0^0(980) \rightarrow f_0(980)$.

As shown on the left of Fig. 1, in order to focus solely on the contribution from $f_0(980) \rightarrow a_0^0(980)$, it is necessary to eliminate the influence caused by different X and Y particles, while adding the contribution shown on the right of Fig. 1. Based on the two Feynman diagrams, the mixing intensity ξ_{fa} for the transition $f_0(980) \rightarrow a_0^0(980)$ can be defined as follows [39]:

Fig. 1. The Feynman diagram for $X \rightarrow Y f_0(980) \rightarrow Y a_0^0(980) \rightarrow Y \pi^0 \eta$ (left) and $X \rightarrow Y f_0(980) \rightarrow Y \pi \pi$ (right) is shown in [39].

$$\begin{aligned} \xi_{fa}(s) &= \frac{d\Gamma_{X \rightarrow Y f_0(980) \rightarrow Y a_0^0(980) \rightarrow Y \pi^0 \eta}(s)}{d\Gamma_{X \rightarrow Y f_0(980) \rightarrow Y \pi \pi}(s)} \\ &= \frac{|D_{a_0 f_0}|^2 \Gamma_{\pi \eta}^a}{|D_{a_0}|^2 \Gamma_{\pi \pi}^f}, \end{aligned} \quad (6)$$

where s is the invariant mass squared of the two mesons in the final state.

Similarly, for the reaction $X \rightarrow Y a_0^0(980) \rightarrow Y f_0(980) \rightarrow Y \pi \pi$ in Fig. 2, the mixing intensity ξ_{af} for the transition $a_0^0(980) \rightarrow f_0(980)$ is defined as follows [39]:

$$\begin{aligned} \xi_{af}(s) &= \frac{d\Gamma_{X \rightarrow Y a_0^0(980) \rightarrow Y f_0(980) \rightarrow Y \pi \pi}(s)}{d\Gamma_{X \rightarrow Y a_0^0(980) \rightarrow Y \pi^0 \eta}(s)} \\ &= \frac{|D_{a_0 f_0}|^2 \Gamma_{\pi \pi}^f}{|D_{f_0}|^2 \Gamma_{\pi \eta}^a}. \end{aligned} \quad (7)$$

However, the physical quantities that can be directly measured by experiments are the integrated mixing intensities, which are defined as [35]:

$$\bar{\xi}_{fa} = \int_{s'_{\min}}^{s'_{\max}} ds \frac{\sqrt{s} |D_{a_0 f_0}(s)|^2 \Gamma_{\pi \eta}^a(s)}{|D_{f_0}(s) D_{a_0}(s)|^2} \bigg/ \int_{s'_{\min}}^{s'_{\max}} ds \frac{\sqrt{s}}{|D_{f_0}(s)|^2} \Gamma_{\pi \pi}^f(s), \quad (8)$$

and

$$\bar{\xi}_{af} = \int_{s'_{\min}}^{s'_{\max}} ds \frac{\sqrt{s} |D_{a_0 f_0}(s)|^2 \Gamma_{\pi \pi}^f(s)}{|D_{f_0}(s) D_{a_0}(s)|^2} \bigg/ \int_{s'_{\min}}^{s'_{\max}} ds \frac{\sqrt{s}}{|D_{a_0}(s)|^2} \Gamma_{\pi \eta}^a(s), \quad (9)$$

where the terms $s'_{\min}$ and $s'_{\max}$ denote the minimum and maximum values of the invariant mass cuts, respectively.

III. DECAY AMPLITUDES AND CP ASYMMETRIES

Following the treatment of B decays in Refs. [9, 10], the total decay amplitude for the process $D^\pm \rightarrow f_0(980)[a_0^0(980)]\pi^\pm \rightarrow \pi^\pm \pi^- \pi^\pm$, incorporating $a_0^0(980) - f_0(980)$ mixing, can be expressed as:

$$\begin{aligned} \mathcal{M}(D^+ \rightarrow \pi^+ \pi^- \pi^+) &= \frac{g_{f_0 \pi \pi}}{D_{f_0}} \mathcal{M}(D^+ \rightarrow f_0 \pi^+) \\ &+ \frac{g_{f_0 \pi \pi} D_{a_0 f_0}}{D_{a_0} D_{f_0} - D_{a_0 f_0}^2} \mathcal{M}(D^+ \rightarrow a_0^0 \pi^+), \end{aligned} \quad (10)$$

where $g_{f_0 \pi \pi}$ is the coupling constant, and $\mathcal{M}(D^+ \rightarrow f_0 \pi^+)$ and $\mathcal{M}(D^+ \rightarrow a_0^0 \pi^+)$ are the decay amplitudes of the processes $D^+ \rightarrow f_0(980)\pi^+$ and $D^+ \rightarrow a_0(980)\pi^+$, respectively.

For the two weak decays $D^+ \rightarrow f_0(980)\pi^+$ and $D^+ \rightarrow a_0(980)\pi^+$, the corresponding effective Hamiltonian can be expressed as [40, 41]:

$$\begin{aligned} H_{\Delta C=1} &= \frac{G_F}{\sqrt{2}} \left\{ \left[\sum_{q=d,s} V_{uq} V_{cq}^* (c_1 O_1^q + c_2 O_2^q) \right] \right. \\ &\quad \left. - V_{ub} V_{cb}^* \sum_{i=3}^6 c_i O_i \right\} + \text{h.c.}, \end{aligned} \quad (11)$$

where G_F is the Fermi constant, $V_{q_1 q_2}$ (q_1 and q_2 represent quarks) are the CKM matrix elements, c_i ($i = 1, \dots, 6$)

Fig. 2. The Feynman diagram for $X \rightarrow Y a_0^0(980) \rightarrow Y f_0(980) \rightarrow Y \pi \pi$ (left) and $X \rightarrow Y a_0^0(980) \rightarrow Y \pi^0 \eta$ (right) is shown.

are the Wilson coefficients, and the four-quark operators O_i are

$$\begin{aligned} O_1^q &= \bar{u}_\alpha \gamma_\mu (1 - \gamma_5) q_\beta \bar{q}_\beta \gamma^\mu (1 - \gamma_5) c_\alpha, \\ O_2^q &= \bar{u} \gamma_\mu (1 - \gamma_5) q \bar{q} \gamma^\mu (1 - \gamma_5) c, \\ O_3 &= \bar{u} \gamma_\mu (1 - \gamma_5) c \sum_{q'} \bar{q}' \gamma^\mu (1 - \gamma_5) q', \\ O_4 &= \bar{u}_\alpha \gamma_\mu (1 - \gamma_5) c_\beta \sum_{q'} \bar{q}'_\beta \gamma^\mu (1 - \gamma_5) q'_\alpha, \\ O_5 &= \bar{u} \gamma_\mu (1 - \gamma_5) c \sum_{q'} \bar{q}' \gamma^\mu (1 + \gamma_5) q', \\ O_6 &= \bar{u}_\alpha \gamma_\mu (1 - \gamma_5) c_\beta \sum_{q'} \bar{q}'_\beta \gamma^\mu (1 + \gamma_5) q'_\alpha, \end{aligned} \quad (12)$$

with O_{1-2}^q being tree operators, O_{3-6} being QCD penguin operators, α, β as color indices, and the sum over q' runs over all light flavor quarks.

In our calculations, we often refer to the decay constants and form factors generally. The decay constants of the scalar meson S and the pseudoscalar meson P are defined as, respectively [42]

$$\langle S(p) | \bar{q}_2 \gamma_\mu q_1 | 0 \rangle = \bar{f}_S p_\mu, \quad \langle P(p) | \bar{q}_2 \gamma_\mu \gamma_5 q_1 | 0 \rangle = -i f_P p_\mu. \quad (13)$$

The form factors of $D \rightarrow S, P$ are defined by [43]:

$$\begin{aligned} \langle P(p') | \hat{V}_\mu | D(p) \rangle &= \left(p_\mu - \frac{m_D^2 - m_P^2}{q^2} q_\mu \right) F_1^{DP}(q^2) \\ &\quad + \frac{m_D^2 - m_P^2}{q^2} q_\mu F_0^{DP}(q^2), \\ \langle S(p') | \hat{A}_\mu | D(p) \rangle &= -i \left[\left(P_\mu - \frac{m_D^2 - m_S^2}{q^2} q_\mu \right) F_1^{DS}(q^2) \right. \\ &\quad \left. + \frac{m_D^2 - m_S^2}{q^2} q_\mu F_0^{DS}(q^2) \right], \end{aligned} \quad (14)$$

where $P_\mu = (p + p')_\mu$, $q_\mu = (p - p')_\mu$, $\hat{V}_\mu$, and $\hat{A}_\mu$ are the weak vector and axial-vector currents, respectively. $\hat{V}_\mu = \bar{q}_f \gamma_\mu c$ and $\hat{A}_\mu = \bar{q}_f \gamma_\mu \gamma_5 c$, with q_f being the quarks generated from the decay of the c quark. As for the $F(q^2)$, we use the 3-parameter parametrization:

$$F(q^2) = \frac{F(0)}{1 - a(q^2/m_D^2) + b(q^2/m_D^2)^2}. \quad (15)$$

For $D \rightarrow SP$ decays, the relevant form factors adopted in this work are $F_0^{DS}(q^2)$ and $F_0^{DP}(q^2)$.

The factorization amplitudes for the $D \rightarrow SP$ decays are given by [42]:

$$\begin{aligned} X^{(DS,P)} &= \langle P(q) | (V - A)_\mu | 0 \rangle \langle S(p) | (V - A)^\mu | D(p_D) \rangle, \\ X^{(DP,S)} &= \langle S(q) | (V - A)_\mu | 0 \rangle \langle P(p) | (V - A)^\mu | D(p_D) \rangle. \end{aligned} \quad (16)$$

In the two-quark model with ideal mixing for $f_0(980)$ and $\sigma(600)$, $f_0(980)$ is characterized as a pure $s\bar{s}$ state, while $\sigma(600)$ is identified as an $n\bar{n}$ state, where $n\bar{n} \equiv (\bar{u}u + \bar{d}d)/\sqrt{2}$. Nevertheless, experimental evidence suggests that $f_0(980)$ does not consist solely of an $s\bar{s}$ configuration. A notable example is the observation of $\Gamma(J/\psi \rightarrow f_0 \omega) \approx \frac{1}{2} \Gamma(J/\psi \rightarrow f_0 \phi)$ [44], which demonstrates unequivocally the presence of both non-strange and strange quark components within $f_0(980)$. Consequently, it is imperative that the isoscalar states $\sigma(600)$ and $f_0(980)$ exhibit a mixing phenomenon, like

$$\begin{aligned} |f_0(980)\rangle &= |s\bar{s}\rangle \cos \theta + |n\bar{n}\rangle \sin \theta, \\ |\sigma(600)\rangle &= -|s\bar{s}\rangle \sin \theta + |n\bar{n}\rangle \cos \theta, \end{aligned} \quad (17)$$

where θ is the mixing angle of the $f_0(980)$ and $\sigma(600)$.

Within the naive factorization approach [45], the decay amplitudes of $D^+ \rightarrow f_0 \pi^+$ and $D^+ \rightarrow a_0^0 \pi^+$ are

$$\begin{aligned} \mathcal{M}(D^+ \rightarrow f_0 \pi^+) &= \frac{G_F}{\sqrt{2}} \left\{ V_{ud} V_{cd}^* \left(\frac{\alpha}{\sqrt{2}} a_1 \bar{f}_{f_0}^d X_{f_0}^{D\pi} - a_2 Y_\pi^{Df_0} \right) \right. \\ &\quad + V_{us} V_{cs}^* \beta a_1 \bar{f}_{f_0}^s X_{f_0}^{D\pi} + V_{ub} V_{cb}^* \left[-a_3 \left(\frac{\alpha}{\sqrt{2}} \bar{f}_{f_0}^u X_{f_0}^{D\pi} \right. \right. \\ &\quad \left. \left. + \frac{\alpha}{\sqrt{2}} \bar{f}_{f_0}^d X_{f_0}^{D\pi} + \beta \bar{f}_{f_0}^s X_{f_0}^{D\pi} \right) + a_4 Y_\pi^{Df_0} \right. \\ &\quad \left. \left. - a_5 \left(\frac{\alpha}{\sqrt{2}} \bar{f}_{f_0}^u X_{f_0}^{D\pi} + \frac{\alpha}{\sqrt{2}} \bar{f}_{f_0}^d X_{f_0}^{D\pi} + \beta \bar{f}_{f_0}^s X_{f_0}^{D\pi} \right) \right. \right. \\ &\quad \left. \left. - \frac{2m_\pi^2 a_6}{(m_c + m_d)(m_u + m_d)} Y_\pi^{Df_0} \right] \right\}, \\ \mathcal{M}(D^+ \rightarrow a_0^0 \pi^+) &= \frac{G_F}{\sqrt{2}} \left\{ V_{ud} V_{cd}^* \left(-\frac{1}{\sqrt{2}} a_1 \bar{f}_{a_0} X_{a_0}^{D\pi} - a_2 Y_\pi^{Da_0} \right) \right. \\ &\quad \left. + V_{ub} V_{cb}^* \left[a_4 Y_\pi^{Da_0} - \frac{2m_\pi^2 a_6}{(m_c + m_d)(m_u + m_d)} Y_\pi^{Da_0} \right] \right\}. \end{aligned} \quad (18)$$

Respectively, $(\alpha, \beta) = (\sin \theta, \cos \theta)$, f_π , $\bar{f}_{f_0}$, and $\bar{f}_{a_0}$ are the decay constants of the π , $f_0(980)$, and $a_0^0(980)$ mesons, respectively. $F_0^{D\pi}$, $F_0^{Df_0}$, and $F_0^{Da_0}$ are the corresponding transition form factors, and a_i are built up from the Wilson coefficients c_i with the form $a_i = c_i + c_{i\pm 1}/N_c^{\text{eff}}$. For compactness, we can use the form: $X_{f_0/a_0}^{D\pi} = (m_D^2 - m_\pi^2) F_0^{D\pi}(m_{f_0/a_0}^2)$ and $Y_\pi^{Df_0/a_0} = f_\pi (m_D^2 - m_{f_0/a_0}^2) F_0^{Df_0/a_0}(m_\pi^2)$.

For the CP-conjugate process $D^\pm \rightarrow \pi^+ \pi^- \pi^\pm$, the dir-

ect CP asymmetry can be expressed in the following form:

$$A_{\text{CP}} = \frac{|\mathcal{M}|^2 - |\bar{\mathcal{M}}|^2}{|\mathcal{M}|^2 + |\bar{\mathcal{M}}|^2}. \quad (19)$$

IV. NUMERICAL RESULTS

From Eqs. (6) to (9), we observe that $\xi_{fa/af}$ and $\bar{\xi}_{fa/af}$ depend on $g_{f_0\pi^0\pi^0}$, $g_{f_0K^+K^-}$, $g_{a_0\pi^0\eta}$, $g_{a_0K^+K^-}$, m_{a_0} , and m_{f_0} . These parameters, compiled from a range of theoretical models and experimental analyses [46–57], are listed in Table 1. The resulting predictions for ξ_{fa} and ξ_{af} , evaluated at $\sqrt{s} = 991.3$ MeV, along with the integrated quantities $\bar{\xi}_{fa}$ and $\bar{\xi}_{af}$, are presented in Table 2 and are consistent with Refs. [35, 39]. The differential mixing intensity satisfies $\xi_{fa} > \xi_{af}$ across different models, whereas the integrated quantities exhibit the opposite ordering, $\bar{\xi}_{fa} < \bar{\xi}_{af}$, making $\bar{\xi}_{af}$ a more favorable observable for experimental measurement. For the decay $D^\pm \rightarrow a_0^0(980)\pi^\pm \rightarrow f_0(980)\pi^\pm \rightarrow \pi^+\pi^-\pi^\pm$, we focus on $\bar{\xi}_{af}$. The majority of

theoretical predictions place $\bar{\xi}_{af}$ in the percent range; models B and C and experiment E yield particularly large values. This also suggests that the $a_0^0(980) - f_0(980)$ mixing mechanism may have a non-negligible impact on CP violation. The mesons $f_0(980)$ and $a_0^0(980)$ can be described within various theoretical frameworks, including conventional $q\bar{q}$ states, $qq\bar{q}\bar{q}$ multiquark configurations, meson-meson bound states, or even scalar glueballs. If these scalar mesons are interpreted as four-quark states, the decay process necessitates the production of an additional quark-antiquark pair compared to the two-quark scenario. Consequently, it is anticipated that the decay amplitude in the four-quark picture would be suppressed relative to that in the two-quark picture when a light scalar meson is involved. Meanwhile, a recent study on the dominance of the $q\bar{q}$ configuration demonstrates that its underlying nature is the color transparency mechanism [58]. For this reason, we adopt the assumption that the $q\bar{q}$ structure is dominant in our analysis.

Substituting Eq. (18) into Eq. (10), one can obtain the total amplitude of the $D^\pm \rightarrow f_0(980)[a_0^0(980)]\pi^\pm \rightarrow \pi^+\pi^-\pi^\pm$ decay with the $a_0^0(980) - f_0(980)$ mixing mechanism.

Figure 3 shows the differential CP asymmetry as a function of $\sqrt{s}$ for several values of the mixing angle θ . The asymmetry varies rapidly and changes sign in the vicinity of the $f_0(980)$ resonance. For $\theta = 0^\circ$ ($|f_0(980)\rangle = |s\bar{s}\rangle$), A_{CP} ranges from -4.40×10^{-4} to 1.52×10^{-4} ; for $\theta = 90^\circ$ ($|f_0(980)\rangle = |n\bar{n}\rangle = 1/\sqrt{2}|u\bar{u} + d\bar{d}\rangle$), it is substantially reduced, ranging from -0.07×10^{-4} to 0.22×10^{-4} . In reality, the $f_0(980)$ is a mixed state with $n\bar{n}$ and $s\bar{s}$. Taking the central value provided in [59], we have examined several examples, which demonstrate that the range of A_{CP} is highly sensitive to the mixing angle when both $n\bar{n}$ and $s\bar{s}$ components are present. The ranges of A_{CP} corresponding to these central angles are summarized in Table 3. From these results, we can clearly see that the $a_0^0(980)$ – $f_0(980)$ mixing mechanism can relatively increase the CP violation, especially for $\theta = 25.1^\circ$ and $\theta = 27^\circ$ conditions, reaching 10^{-4} to 10^{-3} .

In the above analysis, we adopt a fixed number of colors $N_c^{\text{eff}} = 3$ for simplicity [42]. To improve the rigor and accuracy of the analysis, we extract the effective value of N_c^{eff} by fitting to the latest decay branching ratios [44]:

$$\text{BR}(D^+ \rightarrow f_0(980)\pi^+ \rightarrow \pi^+\pi^-\pi^+) = (1.57 \pm 0.32) \times 10^{-4}. \quad (20)$$

Since the decay process $D^+ \rightarrow \pi^+\pi^-\pi^+$ has a three-body final state, the branching fraction of this decay can be expressed as [44]

$$\text{BR} = \frac{\tau_D}{(2\pi)^5 16m_D^2} \int ds |\mathbf{p}_1^*| |\mathbf{p}_3| \int d\Omega_1^* \int d\Omega_3 |\mathcal{M}|^2, \quad (21)$$

where τ_D denotes the lifetime of the $D^\pm$ meson, Ω_1^* and Ω_3 are the solid angles for the final π in the $\pi\pi$ rest frame and for the final π in the D meson rest frame, respectively, and $|\mathbf{p}_1^*|$ and $|\mathbf{p}_3|$ are the norms of the three-momenta of the final-state π in the $\pi\pi$ rest frame and the π in

the D rest frame, respectively, which take the following forms:

$$|\mathbf{p}_1^*| = \frac{\sqrt{\lambda(s, m_\pi^2, m_\pi^2)}}{2\sqrt{s}}, \quad |\mathbf{p}_3| = \frac{\sqrt{\lambda(m_D^2, m_\pi^2, s)}}{2m_D}, \quad (22)$$

where $\lambda(a, b, c)$ is the Källén function with the form $\lambda(a, b, c) = a^2 + b^2 + c^2 - 2(ab + ac + bc)$. It should be noted that $\mathcal{M}$ in Eq. (21) refers to the amplitude of the three-body decay process $D^+ \rightarrow f_0(980)\pi^+ \rightarrow \pi^+\pi^-\pi^+$ without $a_0^0(980)$ – $f_0(980)$ mixing.

In the fitting procedure, we use the central value 1.57×10^{-4} for $\mathcal{B}(D^+ \rightarrow f_0(980)\pi^+ \rightarrow \pi^+\pi^-\pi^+)$. Based on the fitted N_c^{eff} , the CP asymmetries for various mixing angles are obtained, which correct the theoretical deviations from the calculation with a fixed $N_c^{\text{eff}} = 3$. The corresponding results are presented in Table 4. It is shown that non-factorizable contributions have a considerable impact on the predicted CP asymmetries, which are suppressed after including these effects. With the improvement of experimental precision, constraining the range of the mixing angle can also help us further confirm the range of CP asymmetries.

V. SUMMARY AND DISCUSSION

We have studied the direct CP violation in $D^\pm \rightarrow \pi^\pm \pi^+ \pi^-$ decay, incorporating the $a_0^0(980)$ – $f_0(980)$ mixing mechanism within the naive factorization approach. The integrated mixing intensity $\tilde{\xi}_{af}$ is found to be of the order of a percent for several input parameter sets, confirming that this isospin-breaking effect is phenomenologically significant. Applying the mechanism to the CP asymmetry calculation, we find that the differential CP violation is enhanced to $O(10^{-4} - 10^{-3})$ depending on the $f_0(980)$ and $\sigma(600)$ mixing angle θ . Since different experimental and theoretical determinations of θ are not yet mutually consistent, we present results across the full

Fig. 3. (color online) The differential CP -violating asymmetry as a function of $\sqrt{s}$ in the decay $D^\pm \rightarrow f_0(980)[a_0^0(980)]\pi^\pm \rightarrow \pi^+\pi^-\pi^\pm$.

Table 3. Ranges of the direct CP asymmetry A_{CP} for different central mixing angles θ , where $R \equiv g_{f_0 K^+ K^-}^2 / g_{f_0 \pi^+ \pi^-}^2$ measures the ratio of the $f_0(980)$ coupling to $K^+ K^-$ and $\pi^+ \pi^-$.

Experimental implications	Mixing angle	A_{CP}	Reference
pure $s\bar{s}$ state	$\theta = 0^\circ$	-4.40×10^{-4} to 1.52×10^{-4}	...
$\phi \rightarrow f_0 \gamma, f_0 \rightarrow \gamma \gamma$	$\theta = 5^\circ$	-6.78×10^{-4} to 2.35×10^{-4}	[60]
$R = 4.03 \pm 0.14$	$\theta = 25.1^\circ$	-20.21×10^{-4} to 7.55×10^{-4}	[57]

QCD sum rules and a_0 data	$\theta = 41^\circ$	-0.39×10^{-4} to 0.14×10^{-4}	[61]
$R = 1.63 \pm 0.46$	$\theta = 42.3^\circ$	-0.28×10^{-4} to 0.10×10^{-4}	[63]
pure $n\bar{n}$ state	$\theta = 90^\circ$	-0.07×10^{-4} to 0.22×10^{-4}	...

Table 4. The fitted values of N_c^{eff} are based on the decay branching ratio and the recalculated CP asymmetries for different mixing angles.

Experimental implications	Mixing angle	N_c^{eff}	A_{CP}
pure $s\bar{s}$ state	$\theta = 0^\circ$	2.199	-19.94×10^{-5} to 7.09×10^{-5}
$\phi \rightarrow f_0 \gamma, f_0 \rightarrow \gamma \gamma$	$\theta = 5^\circ$	2.216	-20.32×10^{-5} to 7.22×10^{-5}
$R = 4.03 \pm 0.14$	$\theta = 25.1^\circ$	2.376	-19.27×10^{-5} to 6.76×10^{-5}
QCD sum rules and f_0 data	$\theta = 27^\circ$	2.408	-18.72×10^{-5} to 6.55×10^{-5}
$J/\psi \rightarrow f_0 \phi, f_0 \omega$	$\theta = 34^\circ$	2.602	-14.66×10^{-5} to 5.07×10^{-5}
QCD sum rules and a_0 data	$\theta = 41^\circ$	3.172	-1.29×10^{-5} to 0.44×10^{-5}
$R = 1.63 \pm 0.46$	$\theta = 42.3^\circ$	3.424	-1.43×10^{-5} to 4.22×10^{-5}
pure $n\bar{n}$ state	$\theta = 90^\circ$	1.771	-25.47×10^{-5} to 9.66×10^{-5}

range of reported central values rather than adopting a single value. After accounting for non-factorizable effects, the CP asymmetry is reduced but can still reach the order of 10^{-4} . The analysis demonstrates that the $a_0^0(980) - f_0(980)$ mixing mechanism should be systematically considered in amplitude analyses of D or B meson three-body decays.

APPENDIX A: THEORETICAL INPUT PARAMETERS

We adopt the $s_{\min}^{(\prime)}$ and $s_{\max}^{(\prime)}$ from Ref. [35]:

$$s'_{\min} = [(991.3 - 4)\text{MeV}]^2, \quad s'_{\max} = [(991.3 + 4)\text{MeV}]^2, \quad (\text{A1})$$

and

$$s_{\min} = [900\text{MeV}]^2, \quad s_{\max} = [1000\text{MeV}]^2. \quad (\text{A2})$$

We use the Wolfenstein parameterization for the CKM matrix elements, which, up to the order of λ^8 , can be expressed as [64]:

$$\begin{aligned}
V_{ud} &= 1 - \frac{\lambda^2}{2} - \frac{\lambda^4}{8} - \frac{\lambda^6}{16} [1 + 8A^2(\rho^2 + \eta^2)] \\
&\quad - \frac{\lambda^8}{128} [5 - 32A^2(\rho^2 + \eta^2)], \\
V_{cd} &= -\lambda + \frac{\lambda^5}{2} A^2 [1 - 2(\rho + i\eta)] + \frac{\lambda^7}{2} A^2 (\rho + i\eta), \\
V_{us} &= \lambda - \frac{1}{2} A^2 \lambda^7 (\rho^2 + \eta^2), \\
V_{cs} &= 1 - \frac{1}{2} \lambda^2 - \frac{1}{8} \lambda^4 (1 + 4A^2) \\
&\quad - \frac{1}{16} \lambda^6 (1 - 4A^2 + 16A^2(\rho + i\eta)) \\
&\quad - \frac{1}{128} \lambda^8 (5 - 8A^2 + 16A^4), \\
V_{ub} &= \lambda^3 A (\rho - i\eta), \\
V_{cb} &= A \lambda^2 - \frac{\lambda^8}{2} A^3 (\rho^2 + \eta^2), \quad (\text{A3})
\end{aligned}$$

with A , ρ , η , and λ being the Wolfenstein parameters, we use the results in Ref. [65]:

$$\begin{aligned}
\lambda &= 0.22465 \pm 0.00039, \quad A = 0.832 \pm 0.009, \\
\bar{\rho} &= 0.139 \pm 0.016, \quad \bar{\eta} = 0.346 \pm 0.010, \quad (\text{A4})
\end{aligned}$$

where

$$\bar{\rho} = \rho \left(1 - \frac{\lambda^2}{2}\right), \quad \bar{\eta} = \eta \left(1 - \frac{\lambda^2}{2}\right). \quad (\text{A5})$$

The effective Wilson coefficients used in our calculations are taken from Ref. [6]

$$\begin{aligned} c_1 &= -0.6941, & c_2 &= 1.3777, & c_3 &= 0.0652, \\ c_4 &= -0.0627, & c_5 &= 0.0206, & c_6 &= -0.1355. \end{aligned} \quad (\text{A6})$$

For the masses appearing in D decays, we use the following values [65, 59] (in units of GeV):

$$\begin{aligned} m_u &= 0.0035, & m_d &= 0.0063, & m_s &= 0.119, & m_c &= 1.3, \\ m_\eta &= 0.5475, & m_{\pi^\pm} &= 0.1396, & m_{K^\pm} &= 0.4937, & m_{K^0} &= 0.4977, \\ m_{D^\pm} &= 1.870, & m_{f_0(980)} &= 0.990, & m_{a_0^0(980)} &= 0.980. \end{aligned} \quad (\text{A7})$$

For the widths, we use [65] (in units of GeV):

$$\Gamma_{f_0(980)} = 0.074, \quad \Gamma_{a_0^0(980)} = 0.092. \quad (\text{A8})$$

As for the form factors, we use [66, 67]:

$$\begin{aligned} F_0^{D\pi}(0) &= 0.67, \text{ with } a = 0.50, b = 0.01, \\ F_0^{Df_0}(0) &= 0.45, \text{ with } a = 1.36, b = 0.32, \\ F_0^{Da_0}(0) &= 0.55, \text{ with } a = 1.06, b = 0.16. \end{aligned} \quad (\text{A9})$$

The following numerical values for the decay constants are used [42] (in units of GeV):

$$\begin{aligned} f_{\pi^\pm} &= 0.131, & \bar{f}_{f_0(980)}^u &= \bar{f}_{f_0(980)}^d = 0.350 \pm 0.02, \\ \bar{f}_{f_0(980)}^s &= 0.370 \pm 0.02, & \bar{f}_{a_0^0(980)} &= 0.365 \pm 0.02. \end{aligned} \quad (\text{A10})$$
